## Machine Learning

## with Kernel Methods

Michael Arbel, Julien Mairal \& Jean-Philippe Vert
firstname.lastname@m4x.org

## Main goal of this course

## Extend

well-understood, linear statistical learning techniques to
real-world, complicated, structured, high-dimensional data based on
a rigorous mathematical framework
leading to
practical modelling tools and algorithms

## Organization of the course

## Contents

(1) Present the basic mathematical theory of kernel methods.
(2) Introduce algorithms for supervised and unsupervised machine learning with kernels.
(3) Develop a working knowledge of kernel engineering for specific data and applications (graphs, biological sequences, images).
(9) Discuss open research topics related to kernels such as large-scale learning with kernels and "deep kernel learning".

## Practical

- Course homepage with slides, schedules, homework etc...: https://mva-kernel-methods.github.io/course-2021-2022/
- Evaluation: $20 \%$ homework $+40 \%$ data challenge $+40 \%$ exam.

## Outline

(1) Kernel tricks

- The kernel trick
- The representer theorem

## Outline

(1) Kernel tricks

- The kernel trick
- The representer theorem
(2) Kernel Methods: Supervised Learning
- Kernel ridge regression
- Kernel logistic regression
- Large-margin classifiers
- Interlude: convex optimization and duality
- Support vector machines

## Outline

(1) Kernel tricks

- The kernel trick
- The representer theorem
(2) Kernel Methods: Supervised Learning
- Kernel ridge regression
- Kernel logistic regression
- Large-margin classifiers
- Interlude: convex optimization and duality
- Support vector machines
(3) Kernel Methods: Unsupervised Learning
- Kernel PCA
- Kernel K-means and spectral clustering
- A quick note on kernel CCA

## Outline

(4) The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends

- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs
(5) Characterizing probabilities with kernels
- Kernel mean embedding
- The Maximum Mean Discrepancy
- Characteristic kernels

## Outline

(4) The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs
(5) Characterizing probabilities with kernels
- Kernel mean embedding
- The Maximum Mean Discrepancy
- Characteristic kernels
(6) Open Problems and Research Topics
- Multiple Kernel Learning (MKL)
- Large-scale learning with kernels
- Foundations of deep learning from a kernel point of view

## Overview

## Motivations

- Develop versatile algorithms to process and analyze data...
- ...without making any assumptions regarding the type of data (vectors, strings, graphs, images, ...)

The approach

- Develop methods based on pairwise comparisons.
- By imposing constraints on the pairwise comparison function (positive definite kernels), we obtain a general framework for learning from data (optimization in RKHS).

## Representation by pairwise comparisons

## Idea

- Define a "comparison function": $K: \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}$.
- Represent a set of $n$ data points $\mathcal{S}=\left\{\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right\}$ by the $n \times n$ matrix:

$$
[\mathbf{K}]_{i j}:=K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) .
$$

## Representation by pairwise comparisons

## Remarks

- $\mathbf{K}$ is always an $n \times n$ matrix, whatever the nature of data: the same algorithm will work for any type of data (vectors, strings, ...).
- Total modularity between the choice of function $K$ and the choice of the algorithm.
- Poor scalability with respect to the dataset size ( $n^{2}$ to compute and store $\mathbf{K}$ )... but wait until the end of the course to see how to deal with large-scale problems
- We will restrict ourselves to a particular class of pairwise comparison functions.

## Positive Definite (p.d.) Kernels

## Definition

A positive definite (p.d.) kernel on a set $\mathcal{X}$ is a function $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ that is symmetric:

$$
\forall\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \in \mathcal{X}^{2}, \quad K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=K\left(\mathbf{x}^{\prime}, \mathbf{x}\right),
$$

and which satisfies, for all $N \in \mathbb{N},\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{N}\right) \in \mathcal{X}^{N}$ and $\left(a_{1}, a_{2}, \ldots, a_{N}\right) \in \mathbb{R}^{N}$ :

$$
\sum_{i=1}^{N} \sum_{j=1}^{N} a_{i} a_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) \geq 0
$$

## Similarity matrices of p.d. kernels

## Remarks

- Equivalently, a kernel $K$ is p.d. if and only if, for any $N \in \mathbb{N}$ and any set of points $\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{N}\right) \in \mathcal{X}^{N}$, the similarity matrix $[\mathrm{K}]_{i j}:=K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)$ is positive semidefinite.
- Kernel methods are algorithms that take such matrices as input.

## Kernels as inner products

Theorem (Aronszajn, 1950)
$K$ is a p.d. kernel on the set $\mathcal{X}$ if and only if there exists a Hilbert space $\mathcal{H}$ and a mapping

$$
\Phi: \mathcal{X} \mapsto \mathcal{H}
$$

such that, for any $\mathbf{x}, \mathbf{x}^{\prime}$ in $\mathcal{X}$ :

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\left\langle\Phi(\mathbf{x}), \Phi\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}} .
$$

## In case of ...

## Definitions

- An inner product on an $\mathbb{R}$-vector space $\mathcal{H}$ is a mapping $(f, g) \mapsto\langle f, g\rangle_{\mathcal{H}}$ from $\mathcal{H}^{2}$ to $\mathbb{R}$ that is bilinear, symmetric and such that $\langle f, f\rangle_{\mathcal{H}}>0$ for all $f \in \mathcal{H} \backslash\{0\}$.
- A vector space endowed with an inner product is called pre-Hilbert. It is endowed with a norm defined as $\|f\|_{\mathcal{H}}=\langle f, f\rangle_{\mathcal{H}}^{\frac{1}{2}}$.
- A Cauchy sequence $\left(f_{n}\right)_{n \geq 0}$ is a sequence whose elements become progressively arbitrarily close to each other:

$$
\lim _{N \rightarrow+\infty} \sup _{n, m \geq N}\left\|f_{n}-f_{m}\right\|_{\mathcal{H}}=0
$$

- A Hilbert space is a pre-Hilbert space complete for the norm $\|\cdot\|_{\mathcal{H}}$. That is, any Cauchy sequence in $\mathcal{H}$ converges in $\mathcal{H}$.

Completeness is necessary to keep "good" convergence properties of Euclidean spaces in an infinite-dimensional context.

## RKHS Definition

## Definition

Let $\mathcal{X}$ be a set and $\mathcal{H} \subset \mathbb{R}^{\mathcal{X}}$ be a class of functions forming a (real) Hilbert space with inner product $\langle., .\rangle_{\mathcal{H}}$. The function $K: \mathcal{X}^{2} \mapsto \mathbb{R}$ is called a reproducing kernel (r.k.) of $\mathcal{H}$ if
(1) $\mathcal{H}$ contains all functions of the form

$$
\forall \mathbf{x} \in \mathcal{X}, \quad K_{\mathbf{x}}: \mathbf{t} \mapsto K(\mathbf{x}, \mathbf{t})
$$

(2) For every $\mathbf{x} \in \mathcal{X}$ and $f \in \mathcal{H}$ the reproducing property holds:

$$
f(\mathbf{x})=\left\langle f, K_{\mathbf{x}}\right\rangle_{\mathcal{H}} .
$$

If a r.k. exists, then $\mathcal{H}$ is called a reproducing kernel Hilbert space (RKHS).

## RKHS: why do we care?

The principle of RKHS gives us a simple recipe to do machine learning:

- Map data $\mathbf{x}$ in $\mathcal{X}$ to a high-dimensional Hilbert space $\mathcal{H}$ (the RKHS) through a kernel mapping $\Phi: \mathcal{X} \rightarrow \mathcal{H}$, with $\Phi(\mathbf{x})=K_{\mathbf{x}}$.
- In $\mathcal{H}$, consider simple linear models $f(\mathbf{x})=\langle f, \Phi(\mathbf{x})\rangle_{\mathcal{H}}$.
- If $\mathcal{X}=\mathbb{R}^{p}$, a linear function in $\Phi(\mathbf{x})$ may be nonlinear in $\mathbf{x}$.
- For instance, for supervised learning, given training data $\left(y_{i}, \mathbf{x}_{i}\right)_{i=1, \ldots, n}$, we may want to minimize the empirical risk.

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2} .
$$

## RKHS: why do we care?

The principle of RKHS gives us a simple recipe to do machine learning:

- Map data $\mathbf{x}$ in $\mathcal{X}$ to a high-dimensional Hilbert space $\mathcal{H}$ (the RKHS) through a kernel mapping $\Phi: \mathcal{X} \rightarrow \mathcal{H}$, with $\Phi(\mathbf{x})=K_{\mathbf{x}}$.
- In $\mathcal{H}$, consider simple linear models $f(\mathbf{x})=\langle f, \Phi(\mathbf{x})\rangle_{\mathcal{H}}$.
- If $\mathcal{X}=\mathbb{R}^{p}$, a linear function in $\Phi(\mathbf{x})$ may be nonlinear in $\mathbf{x}$.
- For instance, for supervised learning, given training data $\left(y_{i}, \mathbf{x}_{i}\right)_{i=1, \ldots, n}$, we may want to minimize the empirical risk.

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2} .
$$

More formal details to come...

## An equivalent definition of RKHS

## Theorem

The Hilbert space $\mathcal{H} \subset \mathbb{R}^{\mathcal{X}}$ is a RKHS if and only if for any $\mathbf{x} \in \mathcal{X}$, the (linear) mapping:

$$
\begin{aligned}
F: \mathcal{H} & \rightarrow \mathbb{R} \\
f & \mapsto f(\mathbf{x})
\end{aligned}
$$

is continuous.

## An equivalent definition of RKHS

## Theorem

The Hilbert space $\mathcal{H} \subset \mathbb{R}^{\mathcal{X}}$ is a RKHS if and only if for any $\mathbf{x} \in \mathcal{X}$, the (linear) mapping:

$$
\begin{aligned}
F: \mathcal{H} & \rightarrow \mathbb{R} \\
f & \mapsto f(\mathbf{x})
\end{aligned}
$$

is continuous.

## Corollary

Convergence in a RKHS implies pointwise convergence, i.e., if $\left(f_{n}\right)_{n \in \mathbb{N}}$ converges to $f$ in $\mathcal{H}$, then $\left(f_{n}(\mathbf{x})\right)_{n \in \mathbb{N}}$ converges to $f(\mathbf{x})$ for any $\mathbf{x} \in \mathcal{X}$.

## Proof (Converse)

## If $f \mapsto f(\mathbf{x})$ is continuous then $\mathcal{H}$ is a RKHS

Conversely, let us assume that for any $\mathbf{x} \in \mathcal{X}$ the linear form $f \in \mathcal{H} \mapsto f(\mathbf{x})$ is continuous.
Then by Riesz representation theorem (general property of Hilbert spaces) there exists a unique $g_{x} \in \mathcal{H}$ such that:

$$
f(\mathbf{x})=\left\langle f, g_{\mathbf{x}}\right\rangle_{\mathcal{H}}
$$

The function $K(\mathbf{x}, \mathbf{y})=g_{\mathbf{x}}(\mathbf{y})$ is then a r.k. for $\mathcal{H}$.

## Uniqueness of r.k. and RKHS

## Theorem

- If $\mathcal{H}$ is a RKHS, then it has a unique r.k.
- Conversely, a function $K$ can be the r.k. of at most one RKHS.

## Uniqueness of r.k. and RKHS

## Theorem

- If $\mathcal{H}$ is a RKHS, then it has a unique r.k.
- Conversely, a function $K$ can be the r.k. of at most one RKHS.

## Consequence

This shows that we can talk of "the" kernel of a RKHS, or "the" RKHS of a kernel.

## Proof

## If a r.k. exists then it is unique

Let $K$ and $K^{\prime}$ be two r.k. of a RKHS $\mathcal{H}$. Then for any $\mathbf{x} \in \mathcal{X}$ :

$$
\begin{aligned}
\left\|K_{\mathrm{x}}-K_{\mathrm{x}}^{\prime}\right\|_{\mathcal{H}}^{2} & =\left\langle K_{\mathrm{x}}-K_{\mathbf{x}}^{\prime}, K_{\mathrm{x}}-K_{\mathrm{x}}^{\prime}\right\rangle_{\mathcal{H}} \\
& =\left\langle K_{\mathrm{x}}-K_{\mathbf{x}}^{\prime}, K_{\mathrm{x}}\right\rangle_{\mathcal{H}}-\left\langle K_{\mathrm{x}}-K_{\mathbf{x}}^{\prime}, K_{\mathrm{x}}^{\prime}\right\rangle_{\mathcal{H}} \\
& =K_{\mathrm{x}}(\mathbf{x})-K_{\mathrm{x}}^{\prime}(\mathbf{x})-K_{\mathrm{x}}(\mathbf{x})+K_{\mathrm{x}}^{\prime}(\mathbf{x}) \\
& =0 .
\end{aligned}
$$

This shows that $K_{\mathrm{x}}=K_{\mathrm{x}}^{\prime}$ as functions, i.e., $K_{\mathrm{x}}(\mathbf{y})=K_{\mathrm{x}}^{\prime}(\mathbf{y})$ for any $\mathbf{y} \in \mathcal{X}$. In other words, $\mathrm{K}=\mathrm{K}^{\prime}$.

## Proof

## If a r.k. exists then it is unique

Let $K$ and $K^{\prime}$ be two r.k. of a RKHS $\mathcal{H}$. Then for any $\mathbf{x} \in \mathcal{X}$ :

$$
\begin{aligned}
\left\|K_{\mathrm{x}}-K_{\mathrm{x}}^{\prime}\right\|_{\mathcal{H}}^{2} & =\left\langle K_{\mathrm{x}}-K_{\mathrm{x}}^{\prime}, K_{\mathrm{x}}-K_{\mathrm{x}}^{\prime}\right\rangle_{\mathcal{H}} \\
& =\left\langle K_{\mathrm{x}}-K_{\mathbf{x}}^{\prime}, K_{\mathrm{x}}\right\rangle_{\mathcal{H}}-\left\langle K_{\mathrm{x}}-K_{\mathbf{x}}^{\prime}, K_{\mathbf{x}}^{\prime}\right\rangle_{\mathcal{H}} \\
& =K_{\mathrm{x}}(\mathbf{x})-K_{\mathrm{x}}^{\prime}(\mathbf{x})-K_{\mathrm{x}}(\mathbf{x})+K_{\mathrm{x}}^{\prime}(\mathbf{x}) \\
& =0
\end{aligned}
$$

This shows that $K_{\mathrm{x}}=K_{\mathrm{x}}^{\prime}$ as functions, i.e., $K_{\mathrm{x}}(\mathbf{y})=K_{\mathrm{x}}^{\prime}(\mathbf{y})$ for any $\mathbf{y} \in \mathcal{X}$. In other words, $\mathrm{K}=\mathrm{K}^{\prime}$.

The RKHS of a r.k. $K$ is unique
Left as exercise.

## An important result

Theorem
A function $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ is p.d. if and only if it is a r.k.

## Proof

A r.k. is p.d.
(1) A r.k. is symmetric because, for any $(\mathbf{x}, \mathbf{y}) \in \mathcal{X}^{2}$ :

$$
K(\mathbf{x}, \mathbf{y})=\left\langle K_{\mathbf{x}}, K_{\mathbf{y}}\right\rangle_{\mathcal{H}}=\left\langle K_{\mathbf{y}}, K_{\mathbf{x}}\right\rangle_{\mathcal{H}}=K(\mathbf{y}, \mathbf{x}) .
$$

(2) It is p.d. because for any $N \in \mathbb{N},\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{N}\right) \in \mathcal{X}^{N}$, and $\left(a_{1}, a_{2}, \ldots, a_{N}\right) \in \mathbb{R}^{N}$ :

$$
\begin{aligned}
\sum_{i, j=1}^{N} a_{i} a_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) & =\sum_{i, j=1}^{N} a_{i} a_{j}\left\langle K_{\mathbf{x}_{i}}, K_{\mathbf{x}_{j}}\right\rangle_{\mathcal{H}} \\
& =\left\|\sum_{i=1}^{N} a_{i} K_{\mathbf{x}_{i}}\right\|_{\mathcal{H}}^{2} \\
& \geq 0 . \quad \square
\end{aligned}
$$

## Proof

A p.d. kernel is a r.k. (1/4)

- Let $\mathcal{H}_{0}$ be the vector subspace of $\mathbb{R}^{\mathcal{X}}$ spanned by the functions $\left\{K_{x}\right\}_{\mathbf{x} \in \mathcal{X}}$.
- For any $f, g \in \mathcal{H}_{0}$, given by:

$$
f=\sum_{i=1}^{m} a_{i} K_{\mathbf{x}_{i}}, \quad g=\sum_{j=1}^{n} b_{j} K_{\mathbf{y}_{j}}
$$

let:

$$
\langle f, g\rangle_{\mathcal{H}_{0}}:=\sum_{i, j} a_{i} b_{j} K\left(\mathbf{x}_{i}, \mathbf{y}_{j}\right)
$$

## Proof

A p.d. kernel is a r.k. (2/4)

- $\langle f, g\rangle_{\mathcal{H}_{0}}$ does not depend on the expansion of $f$ and $g$ because:

$$
\langle f, g\rangle_{\mathcal{H}_{0}}=\sum_{i=1}^{m} a_{i} g\left(\mathbf{x}_{i}\right)=\sum_{j=1}^{n} b_{j} f\left(\mathbf{y}_{j}\right) .
$$

- This also shows that $\langle., .\rangle_{\mathcal{H}_{0}}$ is a symmetric bilinear form.
- This also shows that for any $\mathbf{x} \in \mathcal{X}$ and $f \in \mathcal{H}_{0}$ :

$$
\left\langle f, K_{\mathbf{x}}\right\rangle_{\mathcal{H}_{0}}=f(\mathbf{x})
$$

## Proof

A p.d. kernel is a r.k. $(3 / 4)$

- $K$ is assumed to be p.d., therefore:

$$
\|f\|_{\mathcal{H}_{0}}^{2}=\sum_{i, j=1}^{m} a_{i} a_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) \geq 0
$$

In particular Cauchy-Schwarz is valid with $\langle., \text {. }\rangle_{\mathcal{H}_{0}}$.

- By Cauchy-Schwarz, we deduce that $\forall \mathbf{x} \in \mathcal{X}$ :

$$
|f(\mathbf{x})|=\left|\left\langle f, K_{\mathbf{x}}\right\rangle_{\mathcal{H}_{0}}\right| \leq\|f\|_{\mathcal{H}_{0}} \cdot K(\mathbf{x}, \mathbf{x})^{\frac{1}{2}}
$$

therefore $\|f\|_{\mathcal{H}_{0}}=0 \Longrightarrow f=0$.

- $\mathcal{H}_{0}$ is therefore a pre-Hilbert space endowed with the inner product $\langle., .\rangle_{\mathcal{H}_{0}}$.

## Proof

## A p.d. kernel is a r.k. (4/4)

- For any Cauchy sequence $\left(f_{n}\right)_{n \geq 0}$ in $\left(\mathcal{H}_{0},\langle., .\rangle_{\mathcal{H}_{0}}\right)$, we note that:
$\forall(\mathbf{x}, m, n) \in \mathcal{X} \times \mathbb{N}^{2}, \quad\left|f_{m}(\mathbf{x})-f_{n}(\mathbf{x})\right| \leq\left\|f_{m}-f_{n}\right\|_{\mathcal{H}_{0}} . K(\mathbf{x}, \mathbf{x})^{\frac{1}{2}}$.
Therefore for any $\mathbf{x}$ the sequence $\left(f_{n}(\mathbf{x})\right)_{n \geq 0}$ is Cauchy in $\mathbb{R}$ and has therefore a limit.
- If we add to $\mathcal{H}_{0}$ the functions defined as the pointwise limits of Cauchy sequences, then the space becomes complete and is therefore a Hilbert space, with $K$ as r.k. (up to a few technicalities, left as exercise).

## Application: back to Aronzsajn's theorem

Theorem (Aronszajn, 1950)
$K$ is a p.d. kernel on the set $\mathcal{X}$ if and only if there exists a Hilbert space $\mathcal{H}$ and a mapping

$$
\Phi: \mathcal{X} \mapsto \mathcal{H},
$$

such that, for any $\mathbf{x}, \mathbf{x}^{\prime}$ in $\mathcal{X}$ :

$$
K\left(\mathbf{x}, \mathrm{x}^{\prime}\right)=\left\langle\Phi(\mathrm{x}), \Phi\left(\mathrm{x}^{\prime}\right)\right\rangle_{\mathcal{H}} .
$$

## Proof of Aronzsajn's theorem

- If $K$ is p.d. over a set $\mathcal{X}$ then it is the r.k. of a Hilbert space $\mathcal{H} \subset \mathbb{R}^{\mathcal{X}}$.
- Let the mapping $\Phi: \mathcal{X} \rightarrow \mathcal{H}$ defined by:

$$
\forall \mathbf{x} \in \mathcal{X}, \quad \Phi(\mathbf{x})=K_{\mathbf{x}} .
$$

- By the reproducing property we have:

$$
\forall(\mathbf{x}, \mathbf{y}) \in \mathcal{X}^{2}, \quad\langle\Phi(\mathbf{x}), \Phi(\mathbf{y})\rangle_{\mathcal{H}}=\left\langle K_{\mathbf{x}}, K_{\mathbf{y}}\right\rangle_{\mathcal{H}}=K(\mathbf{x}, \mathbf{y})
$$

## The linear kernel

Take $\mathcal{X}=\mathbb{R}^{d}$ and the linear kernel:

$$
K(\mathbf{x}, \mathbf{y})=\langle\mathbf{x}, \mathbf{y}\rangle_{\mathbb{R}^{d}} .
$$

## Theorem

The RKHS of the linear kernel is the set of linear functions of the form

$$
f_{\mathbf{w}}(\mathbf{x})=\langle\mathbf{w}, \mathbf{x}\rangle_{\mathbb{R}^{d}} \quad \text { for } \quad \mathbf{w} \in \mathbb{R}^{d}
$$

endowed with the inner product

$$
\forall \mathbf{w}, \mathbf{v} \in \mathbb{R}^{d}, \quad\left\langle f_{\mathbf{w}}, f_{\mathbf{v}}\right\rangle_{\mathcal{H}}=\langle\mathbf{w}, \mathbf{v}\rangle_{\mathbb{R}^{d}}
$$

and corresponding norm

$$
\forall \mathbf{w} \in \mathbb{R}^{d}, \quad\left\|f_{\mathbf{w}}\right\|_{\mathcal{H}}=\|\mathbf{w}\|_{2}
$$

## Proof

The set $\mathcal{H}$ of functions described in the theorem is the dual of $\mathbb{R}^{d}$, hence it is a Hilbert space:

$$
\mathcal{H}=\left\{f_{\mathbf{w}}(\mathbf{x})=\langle\mathbf{w}, \mathbf{x}\rangle_{\mathbb{R}^{d}}: \mathbf{w} \in \mathbb{R}^{d}\right\}
$$

- $\mathcal{H}$ contains all functions of the form $K_{\mathbf{w}}: \mathbf{x} \mapsto\langle\mathbf{w}, \mathbf{x}\rangle_{\mathbb{R}^{d}}$.
- For every $\mathbf{x}$ in $\mathbb{R}^{d}$, and $f_{\mathrm{w}}$ in $\mathcal{H}$,

$$
f_{\mathbf{w}}(\mathbf{x})=\langle\mathbf{w}, \mathbf{x}\rangle_{\mathbb{R}^{d}}=\left\langle f_{\mathbf{w}}, K_{\mathbf{x}}\right\rangle_{\mathcal{H}} .
$$

$\mathcal{H}$ is thus the RKHS of the linear kernel.

## The polynomial kernel

Let us find the RKHS of the polynomial kernel of degree 2:

$$
\forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^{d}, \quad K(\mathbf{x}, \mathbf{y})=\langle\mathbf{x}, \mathbf{y}\rangle_{\mathbb{R}^{d}}^{2}=\left(\mathbf{x}^{\top} \mathbf{y}\right)^{2}
$$

## The polynomial kernel

Let us find the RKHS of the polynomial kernel of degree 2:

$$
\forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^{d}, \quad K(\mathbf{x}, \mathbf{y})=\langle\mathbf{x}, \mathbf{y}\rangle_{\mathbb{R}^{d}}^{2}=\left(\mathbf{x}^{\top} \mathbf{y}\right)^{2}
$$

First step: Look for an inner-product.

$$
\begin{aligned}
K(\mathbf{x}, \mathbf{y}) & =\operatorname{trace}\left(\mathbf{x}^{\top} \mathbf{y} \mathbf{x}^{\top} \mathbf{y}\right) \\
& =\operatorname{trace}\left(\mathbf{y}^{\top} \mathbf{x} \mathbf{x}^{\top} \mathbf{y}\right) \\
& =\operatorname{trace}\left(\mathbf{x x}^{\top} \mathbf{y} \mathbf{y}^{\top}\right) \\
& =\left\langle\mathbf{\mathbf { x x } ^ { \top } ,} \mathbf{y y}^{\top}\right\rangle_{\mathrm{F}},
\end{aligned}
$$

where $F$ is the Froebenius norm for matrices in $\mathbb{R}^{d \times d}$. Note that we have proven here that $K$ is p.d.

## The polynomial kernel

Second step: propose a candidate RKHS.
We know that $\mathcal{H}$ contains all the functions

$$
f(\mathbf{x})=\sum_{i} a_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)=\sum_{i} a_{i}\left\langle\mathbf{x}_{i} \mathbf{x}_{i}^{\top}, \mathbf{\mathbf { x } ^ { \top }}\right\rangle_{\mathrm{F}}=\left\langle\sum_{i} a_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\top}, \mathbf{x x}^{\top}\right\rangle_{\mathrm{F}}
$$

Any symmetric matrix in $\mathbb{R}^{d \times d}$ may be decomposed as $\sum_{i} a_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\top}$. Our candidate RKHS $\mathcal{H}$ will be the set of quadratic functions

$$
f_{\mathbf{S}}(\mathbf{x})=\left\langle\mathbf{S}, \mathbf{x x}^{\top}\right\rangle_{\mathrm{F}}=\mathbf{x}^{\top} \mathbf{S} \mathbf{x} \quad \text { for } \quad \mathbf{S} \in \mathcal{S}^{d \times d}
$$

where $\mathcal{S}^{d \times d}$ is the set of symmetric ${ }^{1}$ matrices in $\mathbb{R}^{d \times d}$, endowed with the inner-product $\left\langle f_{\mathbf{S}_{1}}, f_{\mathbf{S}_{2}}\right\rangle_{\mathcal{H}}=\left\langle\mathbf{S}_{1}, \mathbf{S}_{2}\right\rangle_{\mathrm{F}}$.

## The polynomial kernel

Third step: check that the candidate is a Hilbert space. This step is trivial in the present case since it is easy to see that $\mathcal{H}$ a Euclidean space, isomorphic to $\mathcal{S}^{d \times d}$ by $\Phi: \mathbf{S} \mapsto f_{\mathbf{S}}$. Sometimes, things are not so simple and we need to prove the completeness explicitly.

## Fourth step: check that $\mathcal{H}$ is the RKHS.

(1) $\mathcal{H}$ contains all the functions $K_{\mathbf{x}}: \mathbf{t} \mapsto K(\mathbf{x}, \mathbf{t})=\left\langle\mathbf{x} \mathbf{x}^{\top}, \mathbf{t t}^{\top}\right\rangle_{\mathrm{F}}$.
(2) For all $f_{\mathrm{S}}$ in $\mathcal{H}$ and $\mathbf{x}$ in $\mathcal{X}$,

$$
f_{\mathbf{S}}(\mathbf{x})=\left\langle\mathbf{S}, \mathbf{x} \mathbf{x}^{\top}\right\rangle_{\mathbf{F}}=\left\langle f_{\mathbf{S}}, f_{\mathbf{x x}^{\top}}\right\rangle_{\mathcal{H}}=\left\langle f_{\mathbf{S}}, K_{\mathbf{x}}\right\rangle_{\mathcal{H}}
$$

## Remark

All points $\mathbf{x}$ in $\mathcal{X}$ are mapped to a rank-one matrix $\mathbf{x x}^{\top}$, hence to a function $K_{\mathrm{x}}=f_{\mathrm{x} \mathrm{x}^{\top}}$ in $\mathcal{H}$. However, most of points in $\mathcal{H}$ do not admit a pre-image (why?).

Exercise: what is the RKHS of the general polynomial kernel?

## Combining kernels

## Theorem

- If $K_{1}$ and $K_{2}$ are p.d. kernels, then:

$$
\begin{aligned}
& K_{1}+K_{2}, \\
& \quad K_{1} K_{2}, \text { and } \\
& \quad c K_{1}, \text { for } c \geq 0
\end{aligned}
$$

are also p.d. kernels

- If $\left(K_{i}\right)_{i \geq 1}$ is a sequence of p.d. kernels that converges pointwisely to a function $K$ :

$$
\forall\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \in \mathcal{X}^{2}, \quad K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\lim _{n \rightarrow \infty} K_{i}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)
$$

then $K$ is also a p.d. kernel.
Proof: for $K_{1} K_{2}$, see next slide; otherwise, left as exercise

## Proof for $K_{1} K_{2}$ is p.d.

## Proof.

Consider $n$ points in $\mathcal{X}$ and the corresponding $n \times n$ p.s.d. kernel matrices $\mathbf{K}_{1}$ and $\mathbf{K}_{2}$. As p.s.d. matrices, they admit factorizations $\mathbf{K}_{1}=\mathbf{X}^{\top} \mathbf{X}$ and $\mathbf{K}_{2}=\mathbf{Y}^{\top} \mathbf{Y}$. Then,

$$
\begin{aligned}
{[\mathbf{K}]_{i j} } & =\left[\mathbf{K}_{1}\right]_{j i}\left[\mathbf{K}_{2}\right]_{i j} \\
& =\operatorname{trace}\left(\left(\mathbf{x}_{i}^{\top} \mathbf{x}_{j}\right)\left(\mathbf{y}_{j}^{\top} \mathbf{y}_{i}\right)\right) \\
& =\operatorname{trace}\left(\left(\mathbf{y}_{i} \mathbf{x}_{i}^{\top}\right)\left(\mathbf{x}_{j} \mathbf{y}_{j}^{\top}\right)\right) \\
& =\left\langle\mathbf{x}_{i} \mathbf{y}_{i}^{\top}, \mathbf{x}_{j} \mathbf{y}_{j}^{\top}\right\rangle_{\mathbf{F}} . \\
& =\left\langle\mathbf{z}_{i}, \mathbf{z}_{\mathbf{j}}\right\rangle_{\mathbb{R}^{\mathbb{R}^{2}}},
\end{aligned}
$$

where the $\mathbf{x}_{i}$ 's and the $\mathbf{y}_{i}$ 's are the columns of $\mathbf{X}$ and $\mathbf{Y}$, respectively and $\mathbf{z}_{i}=\operatorname{vec}\left(\mathbf{x}_{i} \mathbf{y}_{i}^{\top}\right)$. Thus, $\mathbf{K}$ is p.s.d. and $K=K_{1} K_{2}$ is a p.d. kernel.

## Examples

Theorem
If $K$ is a kernel, then $e^{K}$ is a kernel too.

## Examples

Theorem
If $K$ is a kernel, then $e^{K}$ is a kernel too.
Proof:

$$
e^{K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)}=\lim _{n \rightarrow+\infty} \sum_{i=0}^{n} \frac{K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)^{i}}{i!}
$$

Quizz : which of the following are p.d. kernels?

$$
\text { - } \mathcal{X}=(-1,1), \quad K\left(x, x^{\prime}\right)=\frac{1}{1-x x^{\prime}}
$$

Quizz : which of the following are p.d. kernels?

$$
\begin{aligned}
& \text { - } \mathcal{X}=(-1,1), \quad K\left(x, x^{\prime}\right)=\frac{1}{1-x x^{\prime}} \\
& \text { - } \mathcal{X}=\mathbb{N}, \quad K\left(x, x^{\prime}\right)=2^{x+x^{\prime}}
\end{aligned}

## Remember the RKHS of the linear kernel

$$
\begin{cases}K_{\text {lin }}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) & =\mathbf{x}^{\top} \mathbf{x}^{\prime} . \\ f(\mathbf{x}) & =\mathbf{w}^{\top} \mathbf{x}, \\ \|f\|_{\mathcal{H}} & =\|\mathbf{w}\|_{2} .\end{cases}
$$

## Smoothness functional

## A simple inequality

- By Cauchy-Schwarz we have, for any function $f \in \mathcal{H}$ and any two points $\mathbf{x}, \mathbf{x}^{\prime} \in \mathcal{X}$ :

$$
\begin{aligned}
\left|f(\mathbf{x})-f\left(\mathbf{x}^{\prime}\right)\right| & =\left|\left\langle f, K_{\mathbf{x}}-K_{\mathbf{x}^{\prime}}\right\rangle_{\mathcal{H}}\right| \\
& \leq\|f\|_{\mathcal{H}} \times\left\|K_{\mathbf{x}}-K_{\mathbf{x}^{\prime}}\right\|_{\mathcal{H}} \\
& =\|f\|_{\mathcal{H}} \times d_{K}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)
\end{aligned}
$$

- The norm of a function in the RKHS controls how fast the function varies over $\mathcal{X}$ with respect to the geometry defined by the kernel (Lipschitz with constant $\|f\|_{\mathcal{H}}$ ).

Important message

## Small norm $\Longrightarrow$ slow variations.

## Kernels and RKHS: Summary

- P.d. kernels can be thought of as inner product after embedding the data space $\mathcal{X}$ in some Hilbert space. As such a p.d. kernel defines a metric on $\mathcal{X}$.
- A realization of this embedding is the RKHS, valid without restriction on the space $\mathcal{X}$ nor on the kernel.
- The RKHS is a space of functions over $\mathcal{X}$. The norm of a function in the RKHS is related to its degree of smoothness w.r.t. the metric defined by the kernel on $\mathcal{X}$.
- We will now see some applications of kernels and RKHS in statistics, before coming back to the problem of choosing (and eventually designing) the kernel.

Part 2

## Kernel tricks

## Motivations

Two theoretical results underpin a family of powerful algorithms for data analysis using p.d. kernels, collectively known as kernel methods:

- The kernel trick, based on the representation of p.d. kernels as inner products;
- The representer theorem, based on some properties of the regularization functional defined by the RKHS norm.

## Motivation from supervised learning

For instance, in supervised learning, the goal is to learn a prediction function $f: \mathcal{X} \rightarrow \mathcal{Y}$ given labeled training data $\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n}$ with $\mathbf{x}_{i}$ in $\mathcal{X}$, and $y_{i}$ in $\mathcal{Y}$ :

$$
\min _{f \in \mathcal{F}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)}_{\text {empirical risk, data fit }}+\underbrace{\lambda \Omega(f)}_{\text {regularization }}
$$

(Vapnik, 1995)...

## Motivation from supervised learning

For instance, in supervised learning, the goal is to learn a prediction function $f: \mathcal{X} \rightarrow \mathcal{Y}$ given labeled training data $\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n}$ with $\mathbf{x}_{i}$ in $\mathcal{X}$, and $y_{i}$ in $\mathcal{Y}$ :

$$
\min _{f \in \mathcal{F}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)}_{\text {empirical risk, data fit }}+\underbrace{\lambda \Omega(f)}_{\text {regularization }}
$$

The labels $y_{i}$ are, for instance, in

- $\{-1,+1\}$ for binary classification problems.
- $\{1, \ldots, K\}$ for multi-class classification problems.
- $\mathbb{R}$ for regression problems.
- $\mathbb{R}^{k}$ for multivariate regression problems.

## Motivation from supervised learning

For instance, in supervised learning, the goal is to learn a prediction function $f: \mathcal{X} \rightarrow \mathcal{Y}$ given labeled training data $\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n}$ with $\mathbf{x}_{i}$ in $\mathcal{X}$, and $y_{i}$ in $\mathcal{Y}$ :

$$
\min _{f \in \mathcal{F}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)}_{\text {empirical risk, data fit }}+\underbrace{\lambda \Omega(f)}_{\text {regularization }}
$$

Example with linear models: logistic regression, etc.

- assume there exists a linear relation between $y$ and features $\mathbf{x}$ in $\mathbb{R}^{p}$.
- $f(\mathbf{x})=\mathbf{w}^{\top} \mathbf{x}+b$ is parametrized by $\mathbf{w}, b$ in $\mathbb{R}^{p+1}$;
- $L$ is often a convex loss function;
- $\Omega(f)$ is often the squared $\ell_{2}$-norm $\|\mathbf{w}\|^{2}$.

## Motivation from supervised learning

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2}
$$

- Kernel methods allow you to map data $x$ in $\mathcal{X}$ to a Hilbert space and work with linear forms:

$$
\Phi: \mathcal{X} \rightarrow \mathcal{H} \quad \text { and } \quad f(\mathbf{x})=\langle\Phi(\mathbf{x}), f\rangle_{\mathcal{H}} .
$$

## Motivation from supervised learning

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2} .
$$

First purpose: embed data in a vectorial space where

- many geometrical operations exist (angle computation, projection on linear subspaces, definition of barycenters....).
- one may learn potentially rich infinite-dimensional models.
- regularization is natural and theoretically grounded.

## Motivation from supervised learning

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2} .
$$

First purpose: embed data in a vectorial space where

- many geometrical operations exist (angle computation, projection on linear subspaces, definition of barycenters....).
- one may learn potentially rich infinite-dimensional models.
- regularization is natural and theoretically grounded.

The principle is generic and does not assume anything about the nature of the set $\mathcal{X}$ (vectors, sets, graphs, sequences).

## Motivation from supervised learning

Second purpose: unhappy with the current Euclidean structure?

- lift data to a higher-dimensional space with nicer properties (e.g., linear separability, clustering structure).
- then, the linear form $f(\mathbf{x})=\langle\Phi(\mathbf{x}), f\rangle_{\mathcal{H}}$ in $\mathcal{H}$ may correspond to a non-linear model in $\mathcal{X}$.

## Outline

## The kernel trick

## Proposition

Any algorithm to process finite-dimensional vectors that can be expressed only in terms of pairwise inner products can be applied to potentially infinite-dimensional vectors in the feature space of a p.d. kernel by replacing each inner product evaluation by a kernel evaluation.

Remarks:

- The proof of this proposition is trivial, because the kernel is exactly the inner product in the feature space.
- This trick has huge practical applications.
- Vectors in the feature space are only manipulated implicitly, through pairwise inner products.

Example 1: computing distances in the feature space

$$
\begin{aligned}
d_{K}\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right)^{2} & =\left\|\Phi\left(\mathbf{x}_{1}\right)-\Phi\left(\mathbf{x}_{2}\right)\right\|_{\mathcal{H}}^{2} \\
& =\left\langle\Phi\left(\mathbf{x}_{1}\right)-\Phi\left(\mathbf{x}_{2}\right), \Phi\left(\mathbf{x}_{1}\right)-\Phi\left(\mathbf{x}_{2}\right)\right\rangle_{\mathcal{H}} \\
& =\left\langle\Phi\left(\mathbf{x}_{1}\right), \Phi\left(\mathbf{x}_{1}\right)\right\rangle_{\mathcal{H}}+\left\langle\Phi\left(\mathbf{x}_{2}\right), \Phi\left(\mathbf{x}_{2}\right)\right\rangle_{\mathcal{H}}-2\left\langle\Phi\left(\mathbf{x}_{1}\right), \Phi\left(\mathbf{x}_{2}\right)\right\rangle_{\mathcal{H}} \\
d_{K}\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right)^{2} & =K\left(\mathbf{x}_{1}, \mathbf{x}_{1}\right)+K\left(\mathbf{x}_{2}, \mathbf{x}_{2}\right)-2 K\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right)
\end{aligned}
$$

## Distance for the Gaussian kernel

- The Gaussian kernel with bandwidth $\sigma$ on $\mathbb{R}^{d}$ is:

$$
K(\mathbf{x}, \mathbf{y})=e^{-\frac{\|x-y\|^{2}}{2 \sigma^{2}}},
$$

- $K(\mathbf{x}, \mathbf{x})=1=\|\Phi(\mathbf{x})\|_{\mathcal{H}}^{2}$, so all points are on the unit sphere in the feature space.
- The distance between the images of two points $\mathbf{x}$ and $\mathbf{y}$ in the feature space is given by:

$$
d_{K}(\mathbf{x}, \mathbf{y})=\sqrt{2\left[1-e^{-\frac{\|\mathbf{x}-\mathbf{y}\|^{2}}{2 \sigma^{2}}}\right]}
$$

## Example 2: distance between a point and a set

## Problem

- Let $\mathcal{S}=\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)$ be a finite set of points in $\mathcal{X}$.
- How to define and compute the similarity between any point $\mathbf{x}$ in $\mathcal{X}$ and the set $\mathcal{S}$ ?

## Example 2: distance between a point and a set

## Problem

- Let $\mathcal{S}=\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)$ be a finite set of points in $\mathcal{X}$.
- How to define and compute the similarity between any point $\mathbf{x}$ in $\mathcal{X}$ and the set $\mathcal{S}$ ?

A solution:

- Map all points to the feature space.
- Summarize $\mathcal{S}$ by the barycenter of the points:

$$
\boldsymbol{\mu}:=\frac{1}{n} \sum_{i=1}^{n} \Phi\left(\mathbf{x}_{i}\right) .
$$

- Define the distance between x and $\mathcal{S}$ by:

$$
d_{K}(\mathbf{x}, \mathcal{S}):=\|\Phi(\mathbf{x})-\boldsymbol{\mu}\|_{\mathcal{H}} .
$$

## Computation

## Remark

The barycentre $\boldsymbol{\mu}$ only exists in the feature space in general: it does not necessarily have a pre-image $\mathbf{x}_{\boldsymbol{\mu}}$ such that $\Phi\left(\mathbf{x}_{\boldsymbol{\mu}}\right)=\boldsymbol{\mu}$.

## 1D illustration

- $\mathcal{S}=\{2,3\}$
- Plot $f(x)=d(x, \mathcal{S})$

$K(x, y)=x y$.
(linear)

$K(x, y)=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}}$. with $\sigma=1$.

$K(x, y)=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}}$.
with $\sigma=0.2$.

## 1D illustration

- $\mathcal{S}=\{2,3\}$
- Plot $f(x)=d(x, \mathcal{S})$

$$
K(x, y)=x y .
$$

(linear)

$K(x, y)=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}}$. with $\sigma=1$.

$K(x, y)=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}}$.
with $\sigma=0.2$.

## Remarks

- for the linear kernel, $\mathcal{H}=\mathbb{R}, \mu=2.5$ and $d(x, \mathcal{S})=|x-\mu|$.
- for the Gaussian kernel $d(x, \mathcal{S})=\sqrt{C-\frac{2}{n} \sum_{i=1}^{n} K\left(x_{i}, x\right)}$.

## 2D illustration

- $\mathcal{S}=\left\{(1,1)^{\prime},(1,2)^{\prime},(2,2)^{\prime}\right\}$
- Plot $f(\mathbf{x})=d(\mathbf{x}, \mathcal{S})$

$K(\mathbf{x}, \mathbf{y})=\mathbf{x y}$.
(linear)

$K(\mathbf{x}, \mathbf{y})=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}}$. with $\sigma=1$.

$K(\mathbf{x}, \mathbf{y})=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}}$.
with $\sigma=0.2$.

## 2D illustration

- $\mathcal{S}=\left\{(1,1)^{\prime},(1,2)^{\prime},(2,2)^{\prime}\right\}$
- $\operatorname{Plot} f(\mathbf{x})=d(\mathbf{x}, \mathcal{S})$

$$
K(\mathbf{x}, \mathbf{y})=\mathbf{x y} .
$$

$$
K(\mathbf{x}, \mathbf{y})=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}} .
$$

with $\sigma=1$.

$K(\mathbf{x}, \mathbf{y})=e^{-\frac{(\mathbf{x}-\boldsymbol{y})^{2}}{2 \sigma^{2}}}$.
with $\sigma=0.2$.

## Remark

- as before, the barycenter $\mu$ in $\mathcal{H}$ (which is a single point in $\mathcal{H}$ ) may carry a lot of information about the training data.

## Basic application in discrimination

- $\mathcal{S}_{1}=\left\{(1,1)^{\prime},(1,2)^{\prime}\right\}$ and $\mathcal{S}_{2}=\left\{(1,3)^{\prime},(2,2)^{\prime}\right\}$
- Plot $f(\mathbf{x})=d\left(\mathbf{x}, \mathcal{S}_{1}\right)^{2}-d\left(\mathbf{x}, \mathcal{S}_{2}\right)^{2}$

$K(\mathbf{x}, \mathbf{y})=\mathbf{x y}$.
(linear)

$$
K(\mathbf{x}, \mathbf{y})=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}} .
$$ with $\sigma=1$.

$$
K(\mathbf{x}, \mathbf{y})=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}} .
$$

with $\sigma=0.2$.

## Example 3: Centering data in the feature space

## Problem

- Let $\mathcal{S}=\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)$ be a finite set of points in $\mathcal{X}$ endowed with a p.d. kernel $K$. Let $\mathbf{K}$ be their $n \times n$ Gram matrix: $[\mathbf{K}]_{i j}=K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)$.
- Let $\mu=1 / n \sum_{i=1}^{n} \Phi\left(\mathbf{x}_{i}\right)$ their barycenter, and $\mathbf{u}_{i}=\Phi\left(\mathbf{x}_{i}\right)-\mu$ for $i=1, \ldots, n$ be centered data in $\mathcal{H}$.
- How to compute the centered Gram matrix $\left[\mathbf{K}^{c}\right]_{i, j}=\left\langle\mathbf{u}_{i}, \mathbf{u}_{j}\right\rangle_{\mathcal{H}}$ ?

## Computation

- A direct computation gives, for $0 \leq i, j \leq n$ :

$$
\begin{aligned}
\mathbf{K}_{i, j}^{c} & =\left\langle\Phi\left(\mathbf{x}_{i}\right)-\boldsymbol{\mu}, \Phi\left(\mathbf{x}_{j}\right)-\boldsymbol{\mu}\right\rangle_{\mathcal{H}} \\
& =\left\langle\Phi\left(\mathbf{x}_{i}\right), \Phi\left(\mathbf{x}_{j}\right)\right\rangle_{\mathcal{H}}-\left\langle\boldsymbol{\mu}, \Phi\left(\mathbf{x}_{i}\right)+\Phi\left(\mathbf{x}_{j}\right)\right\rangle_{\mathcal{H}}+\langle\boldsymbol{\mu}, \boldsymbol{\mu}\rangle_{\mathcal{H}} \\
& =\mathbf{K}_{i, j}-\frac{1}{n} \sum_{k=1}^{n}\left(\mathbf{K}_{i, k}+\mathbf{K}_{j, k}\right)+\frac{1}{n^{2}} \sum_{k, l=1}^{n} \mathbf{K}_{k, l} .
\end{aligned}
$$

- This can be rewritten in matricial form:

$$
\mathbf{K}^{c}=\mathbf{K}-\mathbf{U K}-\mathbf{K} \mathbf{U}+\mathbf{U K} \mathbf{U}=(\mathbf{I}-\mathbf{U}) \mathbf{K}(\mathbf{I}-\mathbf{U}),
$$

where $\mathbf{U}_{i, j}=1 / n$ for $1 \leq i, j \leq n$.

## Kernel trick Summary

- The kernel trick is a trivial statement with important applications.
- It can be used to obtain nonlinear versions of well-known linear algorithms, e.g., by replacing the classical inner product by a Gaussian kernel.
- It can be used to apply classical algorithms to non vectorial data (e.g., strings, graphs) by again replacing the classical inner product by a valid kernel for the data.
- It allows in some cases to embed the initial space to a larger feature space and involve points in the feature space with no pre-image (e.g., barycenter).

## Outline

(1) Kernel tricks

- The kernel trick
- The representer theorem
(2) Kernel Methods: Supervised Learning
(3) Kernel Methods: Unsupervised Learning
(4) The Kernel Jungle
(5) Characterizing probabilities with kernels
(6) Open Problems and Research Topics

## Motivation

- An RKHS is a space of (potentially nonlinear) functions, and $\|f\|_{\mathcal{H}}$ measures the smoothness of $f$.
- Given a set of data $\left(\mathbf{x}_{i} \in \mathcal{X}, y_{i} \in \mathbb{R}\right)_{i=1, \ldots, n}$, a natural way to estimate a regression function $f: \mathcal{X} \rightarrow \mathbb{R}$ is to solve something like:

$$
\begin{equation*}
\min _{f \in \mathcal{H}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} \ell\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)}_{\text {empirical risk, data fit }}+\underbrace{\lambda\|f\|_{\mathcal{H}}^{2}}_{\text {regularization }} \tag{1}
\end{equation*}
$$

for a loss function $\ell$ such as $\ell(y, t)=(y-t)^{2}$.

- How to solve in practice this problem, potentially in infinite dimension?

## The Theorem

## Representer Theorem

- Let $\mathcal{X}$ be a set endowed with a p.d. kernel $K, \mathcal{H}$ the corresponding RKHS, and $\mathcal{S}=\left\{\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right\} \subseteq \mathcal{X}$ a finite set of points in $\mathcal{X}$.
- Let $\Psi: \mathbb{R}^{n+1} \rightarrow \mathbb{R}$ be a function of $n+1$ variables, strictly increasing with respect to the last variable.
- Then, any solution to the optimization problem:

$$
\min _{f \in \mathcal{H}} \Psi\left(f\left(\mathbf{x}_{1}\right), \cdots, f\left(\mathbf{x}_{n}\right),\|f\|_{\mathcal{H}}\right)
$$

admits a representation of the form:

$$
\forall \mathbf{x} \in \mathcal{X}, \quad f(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)=\sum_{i=1}^{n} \alpha_{i} K_{\mathrm{x}_{i}}(\mathbf{x})
$$

In other words, the solution lives in a finite-dimensional subspace:

$$
f \in \operatorname{Span}\left(K_{x_{1}}, \ldots, K_{x_{n}}\right)
$$

## Proof (1/2)

- Let $\xi(f)$ be the functional that is minimized in the statement of the representer theorem, and $\mathcal{H}_{\mathcal{S}}$ the linear span in $\mathcal{H}$ of the vectors $K_{\mathbf{x}_{i}}$ :

$$
\mathcal{H}_{\mathcal{S}}=\left\{f \in \mathcal{H}: f(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right),\left(\alpha_{1}, \cdots, \alpha_{n}\right) \in \mathbb{R}^{n}\right\}
$$

- $\mathcal{H}_{\mathcal{S}}$ is a finite-dimensional subspace, therefore any function $f \in \mathcal{H}$ can be uniquely decomposed as:

$$
f=f_{\mathcal{S}}+f_{\perp}
$$

with $f_{\mathcal{S}} \in \mathcal{H}_{\mathcal{S}}$ and $f_{\perp} \perp \mathcal{H}_{\mathcal{S}}$ (by orthogonal projection).

## Proof (2/2)

- $\mathcal{H}$ being a RKHS it holds that:

$$
\forall i=1, \cdots, n, \quad f_{\perp}\left(\mathbf{x}_{i}\right)=\left\langle f_{\perp}, K_{\mathbf{x}_{i}}\right\rangle_{\mathcal{H}}=0
$$

because $K_{\mathbf{x}_{i}}=K\left(\mathbf{x}_{i},.\right) \in \mathcal{H}_{\mathcal{S}}$ and $f_{\perp} \perp \mathcal{H}_{\mathcal{S}}$, therefore:

$$
\forall i=1, \cdots, n, \quad f\left(\mathbf{x}_{i}\right)=f_{\mathcal{S}}\left(\mathbf{x}_{i}\right)
$$

- Pythagoras' theorem in $\mathcal{H}$ then shows that:

$$
\|f\|_{\mathcal{H}}^{2}=\left\|f_{\mathcal{S}}\right\|_{\mathcal{H}}^{2}+\left\|f_{\perp}\right\|_{\mathcal{H}}^{2} .
$$

- As a consequence, $\xi(f) \geq \xi\left(f_{\mathcal{S}}\right)$, with equality if and only if $\left\|f_{\perp}\right\|_{\mathcal{H}}=0$. The minimum of $\Psi$ is therefore necessarily in $\mathcal{H}_{\mathcal{S}}$.

## Remarks

Often the function $\Psi$ has the form:

$$
\Psi\left(f\left(\mathbf{x}_{1}\right), \cdots, f\left(\mathbf{x}_{n}\right),\|f\|_{\mathcal{H}}\right)=c\left(f\left(\mathbf{x}_{1}\right), \cdots, f\left(\mathbf{x}_{n}\right)\right)+\lambda \Omega\left(\|f\|_{\mathcal{H}}\right)
$$

where $c($.$) measures the "fit" of f$ to a given problem (regression, classification, dimension reduction, ...) and $\Omega$ is strictly increasing. This formulation has two important consequences:

- Theoretically, the minimization will enforce the norm $\|f\|_{\mathcal{H}}$ to be "small", which can be beneficial by ensuring a sufficient level of smoothness for the solution (regularization effect).
- Practically, we know by the representer theorem that the solution lives in a subspace of dimension $n$, which can lead to efficient algorithms although the RKHS itself can be of infinite dimension.

## Practical use of the representer theorem $(1 / 2)$

- When the representer theorem holds, we know that we can look for a solution of the form

$$
f(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right), \quad \text { for some } \boldsymbol{\alpha} \in \mathbb{R}^{n}
$$

- For any $j=1, \ldots, n$, we have

$$
f\left(\mathbf{x}_{j}\right)=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)=[\mathbf{K} \alpha]_{j}
$$

- Furthermore,

$$
\|f\|_{\mathcal{H}}^{2}=\left\|\sum_{i=1}^{n} \alpha_{i} K_{\mathbf{x}_{i}}\right\|_{\mathcal{H}}^{2}=\sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_{i} \alpha_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)=\alpha^{\top} K \alpha .
$$

## Practical use of the representer theorem $(2 / 2)$

- Therefore, a problem of the form

$$
\min _{f \in \mathcal{H}} \Psi\left(f\left(\mathbf{x}_{1}\right), \cdots, f\left(\mathbf{x}_{n}\right),\|f\|_{\mathcal{H}}^{2}\right)
$$

is equivalent to the following $n$-dimensional optimization problem:

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}} \Psi\left([\mathbf{K} \boldsymbol{\alpha}]_{1}, \cdots,[\mathbf{K} \boldsymbol{\alpha}]_{n}, \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}\right)
$$

- This problem can usually be solved analytically or by numerical methods; we will see many examples in the next sections.

## Remarks

## Dual interpretations of kernel methods

Most kernel methods have two complementary interpretations:

- A geometric interpretation in the feature space, thanks to the kernel trick. Even when the feature space is "large", most kernel methods work in the linear span of the embeddings of the points available.
- A functional interpretation, often as an optimization problem over (subsets of) the RKHS associated to the kernel.

The representer theorem has important consequences, but it is in fact rather trivial. We are looking for a function $f$ in $\mathcal{H}$ such that for all $\mathbf{x}$ in $\mathcal{X}, f(\mathbf{x})=\left\langle K_{\mathbf{x}}, f\right\rangle_{\mathcal{H}}$. The part $f^{\perp}$ that is orthogonal to the $K_{\mathbf{x}_{i}}$ 's is thus "useless" to explain the training data.

# Kernel Methods <br> Supervised Learning 

## Supervised learning

## Definition

## Given:

- $\mathcal{X}$, a space of inputs,
- $\mathcal{Y}$, a space of outputs,
- $\mathcal{S}_{n}=\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n}$, a training set of (input,output) pairs, the supervised learning problem is to estimate a function $h: \mathcal{X} \rightarrow \mathcal{Y}$ to predict the output for any future input.

## Supervised learning

## Definition

## Given:

- $\mathcal{X}$, a space of inputs,
- $\mathcal{Y}$, a space of outputs,
- $\mathcal{S}_{n}=\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n}$, a training set of (input,output) pairs, the supervised learning problem is to estimate a function $h: \mathcal{X} \rightarrow \mathcal{Y}$ to predict the output for any future input.

Depending on the nature of the output, this covers:

- Regression when $\mathcal{Y}=\mathbb{R}$;
- Classification when $\mathcal{Y}=\{-1,1\}$ or any set of two labels;
- Structured output regression or classification when $\mathcal{Y}$ is more general.

## Example: regression

Task: predict the capacity of a small molecule to inhibit a drug target $\mathcal{X}=$ set of molecular structures (graphs?)
$\mathcal{Y}=\mathbb{R}$

## Example: classification

Task: recognize if an image is a dog or a cat $\mathcal{X}=$ set of images $\left(\mathbb{R}^{d}\right)$
$\mathcal{Y}=\{c a t, \operatorname{dog}\}$

## Example: classification

Task: recognize if an image is a dog or a cat $\mathcal{X}=$ set of images $\left(\mathbb{R}^{d}\right)$
$\mathcal{Y}=\{c a t, \operatorname{dog}\}$

## Example: structured output

Task: translate from Japanese to French $\mathcal{X}=$ finite-length strings of japanese characters
$\mathcal{Y}=$ finite-length strings of french characters

## Supervised learning with kernels: general principles

(1) Express $h: \mathcal{X} \rightarrow \mathcal{Y}$ using a real-valued function $f: \mathcal{Z} \rightarrow \mathbb{R}$ :

- regression $\mathcal{Y}=\mathbb{R}$ :

$$
h(\mathbf{x})=f(\mathbf{x}) \quad \text { with } \quad f: \mathcal{X} \rightarrow \mathbb{R} \quad(\mathcal{Z}=\mathcal{X})
$$

- classification $\mathcal{Y}=\{-1,1\}$ :

$$
h(\mathbf{x})=\operatorname{sign}(f(\mathbf{x})) \quad \text { with } \quad f: \mathcal{X} \rightarrow \mathbb{R} \quad(\mathcal{Z}=\mathcal{X})
$$

- structured output:

$$
h(\mathbf{x})=\arg \max _{\mathbf{y} \in \mathcal{Y}} f(\mathbf{x}, \mathbf{y}) \quad \text { with } \quad f: \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R} \quad(\mathcal{Z}=\mathcal{X} \times \mathcal{Y})
$$

(2) Define an empirical risk function $R_{n}(f)$ to assess how "good" a candidate function $f$ is on the training set $\mathcal{S}_{n}$, typically the average of a loss:

$$
R_{n}(f):=\frac{1}{n} \sum_{i=1}^{n} \ell\left(f\left(\mathbf{x}_{i}\right), \mathbf{y}_{i}\right)
$$

(3) Define a p.d. kernel on $\mathcal{Z}$ and solve

$$
\min _{f \in \mathcal{H},\|f\|_{\mathcal{H}} \leq B} R_{n}(f) \quad \text { or } \min _{f \in \mathcal{H}} R_{n}(f)+\lambda\|f\|_{\mathcal{H}}^{2}
$$

## Remarks

$$
\min _{f \in \mathcal{H}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} \ell\left(f\left(\mathbf{x}_{i}\right), y_{i}\right)}_{\text {empirical risk, data fit }}+\underbrace{\lambda\|f\|_{\mathcal{H}}^{2}}_{\text {regularization }}
$$

- Regularization is important, particularly in high dimension, to prevent overfitting
- When $\mathcal{Z}=\mathbb{R}^{d}$ and $K$ is the linear kernel, $f=f_{w}$ is a linear model and the regularization is $\|\mathbf{w}\|^{2}$
- Using more general spaces $\mathcal{Z}$ and kernels $K$ allows to
- learn non-linear functions over a functional space endowed with a natural regularization (remember, small norm in RKHS = "smooth")
- learn functions over non-vectorial data, such as strings and graphs

We will now see a few methods in more details

## Outline

- Interlude: convex optimization and duality
- Support vector machines
(3) Kernel Methods: Unsupervised Learning

44 The Kernel Jungle
(5) Characterizing probabilities with kernels
(6) Open Problems and Research Topics

## Regression

## Setup

- $\mathcal{X}$ set of inputs
- $\mathcal{Y}=\mathbb{R}$ real-valued outputs
- $\mathcal{S}_{n}=\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n} \in(\mathcal{X} \times \mathbb{R})^{n}$ a training set of $n$ pairs
- Goal $=$ find a function $f: \mathcal{X} \rightarrow \mathbb{R}$ to predict $y$ by $f(\mathbf{x})$

## Regression

## Setup

- $\mathcal{X}$ set of inputs
- $\mathcal{Y}=\mathbb{R}$ real-valued outputs
- $\mathcal{S}_{n}=\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n} \in(\mathcal{X} \times \mathbb{R})^{n}$ a training set of $n$ pairs
- Goal $=$ find a function $f: \mathcal{X} \rightarrow \mathbb{R}$ to predict $y$ by $f(\mathbf{x})$

## Least-square regression over a general functional space

- Let us quantify the error if $f$ predicts $f(\mathbf{x})$ instead of $y$ by the squared error:

$$
\ell(f(\mathbf{x}), y)=(y-f(\mathbf{x}))^{2}
$$

- Fix a set of functions $\mathcal{H}$.
- Least-square regression amounts to finding the function in $\mathcal{H}$ with the smallest empirical risk, called in this case the mean squared error (MSE):

$$
\hat{f} \in \underset{f \in \mathcal{H}}{\arg \min } \frac{1}{n} \sum_{i=1}^{n}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}
$$

- Issues: unstable (especially in large dimensions), overfitting if $\mathcal{H}$ is too "large".

## Kernel ridge regression (KRR)

- Let us now consider a RKHS $\mathcal{H}$, associated to a p.d. kernel $K$ on $\mathcal{X}$.
- KRR is obtained by regularizing the MSE criterion by the RKHS norm:

$$
\begin{equation*}
\hat{f}=\underset{f \in \mathcal{H}}{\arg \min } \frac{1}{n} \sum_{i=1}^{n}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda\|f\|_{\mathcal{H}}^{2} \tag{2}
\end{equation*}
$$

- 1 st effect $=$ prevent overfitting by penalizing non-smooth functions.

## Kernel ridge regression (KRR)

- Let us now consider a RKHS $\mathcal{H}$, associated to a p.d. kernel $K$ on $\mathcal{X}$.
- KRR is obtained by regularizing the MSE criterion by the RKHS norm:

$$
\begin{equation*}
\hat{f}=\underset{f \in \mathcal{H}}{\arg \min } \frac{1}{n} \sum_{i=1}^{n}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda\|f\|_{\mathcal{H}}^{2} \tag{2}
\end{equation*}
$$

- 1st effect $=$ prevent overfitting by penalizing non-smooth functions.
- By the representer theorem, any solution of (2) can be expanded as

$$
\hat{f}(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)
$$

- 2nd effect $=$ simplifying the solution.

## Solving KRR

- Let $\mathbf{y}=\left(y_{1}, \ldots, y_{n}\right)^{\top} \in \mathbb{R}^{n}$
- Let $\boldsymbol{\alpha}=\left(\alpha_{1}, \ldots, \alpha_{n}\right)^{\top} \in \mathbb{R}^{n}$
- Let $\mathbf{K}$ be the $n \times n$ Gram matrix: $\mathbf{K}_{i j}=K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)$
- We can then write:

$$
\left(\hat{f}\left(\mathbf{x}_{1}\right), \ldots, \hat{f}\left(\mathbf{x}_{n}\right)\right)^{\top}=\mathbf{K} \boldsymbol{\alpha}
$$

- The following holds as usual:

$$
\|\hat{f}\|_{\mathcal{H}}^{2}=\boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

- The KRR problem (2) is therefore equivalent to:

$$
\underset{\boldsymbol{\alpha} \in \mathbb{R}^{n}}{\arg \min } \frac{1}{n}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{y})^{\top}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{y})+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

## Solving KRR

$$
\underset{\boldsymbol{\alpha} \in \mathbb{R}^{n}}{\arg \min } \frac{1}{n}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{y})^{\top}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{y})+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

- This is a convex and differentiable function of $\boldsymbol{\alpha}$. Its minimum can therefore be found by setting the gradient in $\boldsymbol{\alpha}$ to zero:

$$
\begin{aligned}
0 & =\frac{2}{n} \mathbf{K}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{y})+2 \lambda \mathbf{K} \boldsymbol{\alpha} \\
& =\mathbf{K}[(\mathbf{K}+\lambda n \mathbf{I}) \boldsymbol{\alpha}-\mathbf{y}]
\end{aligned}
$$

- For $\lambda>0, \mathbf{K}+\lambda n \mathbf{l}$ is invertible (because $\mathbf{K}$ is positive semidefinite) so one solution is to take:

$$
\boldsymbol{\alpha}=(\mathbf{K}+\lambda n \mathbf{l})^{-1} \mathbf{y} .
$$

\text { lambda }=0.0000001
$$

## Remark: uniqueness of the solution

Let us find all $\boldsymbol{\alpha}$ 's that solve

$$
\mathbf{K}[(\mathbf{K}+\lambda n \mathbf{I}) \boldsymbol{\alpha}-\mathbf{y}]=0
$$

- K being a symmetric matrix, it can be diagonalized in an orthonormal basis and $\operatorname{Ker}(\mathbf{K}) \perp \operatorname{Im}(\mathbf{K})$.
- In this basis we see that $(\mathbf{K}+\lambda n \mathbf{I})^{-1}$ leaves $\operatorname{Im}(\mathbf{K})$ and $\operatorname{Ker}(\mathbf{K})$ invariant.
- The problem is therefore equivalent to:

$$
\begin{aligned}
& (\mathbf{K}+\lambda n \mathbf{I}) \boldsymbol{\alpha}-\mathbf{y} \in \operatorname{Ker}(\mathbf{K}) \\
\Leftrightarrow & \boldsymbol{\alpha}-(\mathbf{K}+\lambda n \mathbf{I})^{-1} \mathbf{y} \in \operatorname{Ker}(\mathbf{K}) \\
\Leftrightarrow & \boldsymbol{\alpha}=(\mathbf{K}+\lambda n \mathbf{I})^{-1} \mathbf{y}+\boldsymbol{\epsilon}, \text { with } \mathbf{K} \boldsymbol{\epsilon}=0 .
\end{aligned}
$$

- However, if $\boldsymbol{\alpha}^{\prime}=\boldsymbol{\alpha}+\boldsymbol{\epsilon}$ with $\mathbf{K} \boldsymbol{\epsilon}=0$, then:

$$
\left\|f-f^{\prime}\right\|_{\mathcal{H}}^{2}=\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}^{\prime}\right)^{\top} \mathbf{K}\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}^{\prime}\right)=0
$$

therefore $f=f^{\prime}$. KRR has a unique solution $f \in \mathcal{H}$, which can possibly be expressed by several $\alpha$ 's if $K$ is singular.

## Remark: link with "standard" ridge regression

- Take $\mathcal{X}=\mathbb{R}^{d}$ and the linear kernel $K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\mathbf{x}^{\top} \mathbf{x}^{\prime}$
- Let $\mathbf{X}=\left(\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right)^{\top}$ the $n \times d$ data matrix
- The kernel matrix is then $\mathbf{K}=\mathbf{X X} \mathbf{X}^{\top}$
- The function learned by KRR in that case is linear:

$$
f_{K R R}(\mathbf{x})=\mathbf{w}_{K R R}^{\top} \mathbf{x}
$$

with

$$
\mathbf{w}_{K R R}=\sum_{i=1}^{n} \alpha_{i} \mathbf{x}_{i}=\mathbf{X}^{\top} \boldsymbol{\alpha}=\mathbf{X}^{\top}\left(\mathbf{X} \mathbf{X}^{\top}+\lambda n \mathbf{I}\right)^{-1} \mathbf{y}
$$

## Remark: link with "standard" ridge regression

- On the other hand, the RKHS is the set of linear functions $f(\mathbf{x})=\mathbf{w}^{\top} \mathbf{x}$ and the RKHS norm is $\|f\|_{\mathcal{H}}=\|\mathbf{w}\|$
- We can therefore directly rewrite the original KRR problem (2) as

$$
\begin{aligned}
\arg \min _{\mathbf{w} \in \mathbb{R}^{d}} \frac{1}{n} \sum_{i=1}^{n}\left(y_{i}-\right. & \left.\mathbf{w}^{\top} \mathbf{x}_{i}\right)^{2}+\lambda\|\mathbf{w}\|^{2} \\
& =\arg \min _{\mathbf{w} \in \mathbb{R}^{d}} \frac{1}{n}(\mathbf{y}-\mathbf{X} \mathbf{w})^{\top}(\mathbf{y}-\mathbf{X} \mathbf{w})+\lambda \mathbf{w}^{\top} \mathbf{w}
\end{aligned}
$$

- Setting the gradient to 0 gives the solution:

$$
\mathbf{w}_{R R}=\left(\mathbf{X}^{\top} \mathbf{X}+\lambda n \mathbf{l}\right)^{-1} \mathbf{X}^{\top} \mathbf{y}
$$

- Oups, looks different from $\mathbf{w}_{K R R}=\mathbf{X}^{\top}\left(\mathbf{X X}^{\top}+\lambda n \mathbf{I}\right)^{-1} \mathbf{y} .$. ?

## Remark: link with "standard" ridge regression

## Matrix inversion lemma

For any matrices $B$ and $C$, and $\gamma>0$ the following holds (when it makes sense):

$$
B(C B+\gamma \mathbf{l})^{-1}=(B C+\gamma \mathbf{l})^{-1} B
$$

We deduce that (of course...):

$$
\mathbf{w}_{R R}=\underbrace{\left(\mathbf{X}^{\top} \mathbf{X}+\lambda n \mathbf{I}\right)^{-1}}_{d \times d} \mathbf{X}^{\top} \mathbf{y}=\mathbf{X}^{\top} \underbrace{\left(\mathbf{X} \mathbf{X}^{\top}+\lambda n \mathbf{I}\right)^{-1}}_{n \times n} \mathbf{y}=\mathbf{w}_{K R R}
$$

## Remark: link with "standard" ridge regression

## Matrix inversion lemma

For any matrices $B$ and $C$, and $\gamma>0$ the following holds (when it makes sense):

$$
B(C B+\gamma \mathbf{l})^{-1}=(B C+\gamma \mathbf{l})^{-1} B
$$

We deduce that (of course...):

$$
\mathbf{w}_{R R}=\underbrace{\left(\mathbf{X}^{\top} \mathbf{X}+\lambda n \mathbf{I}\right)^{-1}}_{d \times d} \mathbf{X}^{\top} \mathbf{y}=\mathbf{X}^{\top} \underbrace{\left(\mathbf{X} \mathbf{X}^{\top}+\lambda n \mathbf{I}\right)^{-1}}_{n \times n} \mathbf{y}=\mathbf{w}_{K R R}
$$

Computationally, inverting the matrix is the expensive part, which suggest to implement:

- KRR when $d>n$ (high dimension)
- RR when $d<n$ (many points)

## Robust regression

- The squared error $\ell(t, y)=(t-y)^{2}$ is arbitrary and sensitive to outliers
- Many other loss functions exist for regression, e.g.:

- Any loss function leads to a valid kernel method, which is usually solved by numerical optimization as there is usually no analytical solution beyond the squared error.

## Weighted regression

- Given weights $W_{1}, \ldots, W_{n} \in \mathbb{R}$, a variant of ridge regression is to weight differently the error at different points:

$$
\underset{f \in \mathcal{H}}{\arg \min } \frac{1}{n} \sum_{i=1}^{n} W_{i}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda\|f\|_{\mathcal{H}}^{2}
$$

- By the representer theorem the solution is $f(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)$ where $\boldsymbol{\alpha}$ solves, with $\mathbf{W}=\operatorname{diag}\left(W_{1}, \ldots, W_{n}\right)$ :

$$
\underset{\boldsymbol{\alpha} \in \mathbb{R}^{n}}{\arg \min } \frac{1}{n}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{y})^{\top} \mathbf{W}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{y})+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

## Weighted regression

- Setting the gradient to zero gives

$$
\begin{aligned}
0 & =\frac{2}{n}(\mathbf{K W K} \boldsymbol{\alpha}-\mathbf{K W} \mathbf{y})+2 \lambda \mathbf{K} \boldsymbol{\alpha} \\
& =\frac{2}{n} \mathbf{K} \mathbf{W}^{\frac{1}{2}}\left[\left(\mathbf{W}^{\frac{1}{2}} \mathbf{K} \mathbf{W}^{\frac{1}{2}}+n \lambda \mathbf{I}\right) \mathbf{W}^{-\frac{1}{2}} \boldsymbol{\alpha}-\mathbf{W}^{\frac{1}{2}} \mathbf{y}\right]
\end{aligned}
$$

- A solution is therefore given by

$$
\left(\mathbf{W}^{\frac{1}{2}} \mathbf{K} \mathbf{W}^{\frac{1}{2}}+n \lambda \mathbf{I}\right) \mathbf{W}^{-\frac{1}{2}} \boldsymbol{\alpha}-\mathbf{W}^{\frac{1}{2}} \mathbf{y}=0
$$

therefore

$$
\boldsymbol{\alpha}=\mathbf{W}^{\frac{1}{2}}\left(\mathbf{W}^{\frac{1}{2}} \mathbf{K} \mathbf{W}^{\frac{1}{2}}+n \lambda \mathbf{I}\right)^{-1} \mathbf{W}^{\frac{1}{2}} \mathbf{Y}
$$

## Binary classification

## Setup

- $\mathcal{X}$ set of inputs
- $\mathcal{Y}=\{-1,1\}$ binary outputs
- $\mathcal{S}_{n}=\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n} \in(\mathcal{X} \times \mathcal{Y})^{n}$ a training set of $n$ pairs
- Goal $=$ find a function $f: \mathcal{X} \rightarrow \mathbb{R}$ to predict $y$ by $\operatorname{sign}(f(\mathbf{x}))$

## Binary classification

## Setup

- $\mathcal{X}$ set of inputs
- $\mathcal{Y}=\{-1,1\}$ binary outputs
- $\mathcal{S}_{n}=\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n} \in(\mathcal{X} \times \mathcal{Y})^{n}$ a training set of $n$ pairs
- Goal $=$ find a function $f: \mathcal{X} \rightarrow \mathbb{R}$ to predict $y$ by $\operatorname{sign}(f(\mathbf{x}))$

## The $0 / 1$ loss

- The $0 / 1$ loss measures if a prediction is correct or not:

$$
\left.\ell_{0 / 1}(f(\mathbf{x}), y)\right)=\mathbf{1}(y f(\mathbf{x})<0)= \begin{cases}0 & \text { if } y=\operatorname{sign}(f(\mathbf{x})) \\ 1 & \text { otherwise }\end{cases}
$$

- It is then tempting to learn $f$ by solving:

$$
\min _{f \in \mathcal{H}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} \ell_{0 / 1}\left(f\left(\mathbf{x}_{i}\right), y_{i}\right)}_{\text {misclassification rate }}+\underbrace{\lambda\|f\|_{\mathcal{H}}^{2}}_{\text {regularization }}
$$

- However:
- The problem is non-smooth, and typically NP-hard to solve
- The regularization has no effect since the $0 / 1$ loss is invariant by scaling of $f$
- In fact, no function achieves the minimum when $\lambda>0$ (why?)

## The logistic loss

- An alternative is to define a probabilistic model of $y$ parametrized by $f(\mathbf{x})$, e.g.:

$$
\forall \mathbf{y} \in\{-1,1\}, \quad p(y \mid f(\mathbf{x}))=\frac{1}{1+e^{-y f(\mathbf{x})}}=\sigma(y f(\mathbf{x}))
$$

- The logistic loss is the negative conditional likelihood:

$$
\ell_{\text {logistic }}(f(\mathbf{x}), y)=-\ln p(y \mid f(\mathbf{x}))=\ln \left(1+e^{-y f(\mathbf{x})}\right)
$$

## Kernel logistic regression (KLR)

$$
\begin{aligned}
\hat{f} & =\underset{f \in \mathcal{H}}{\arg \min } \frac{1}{n} \sum_{i=1}^{n} \ell_{\text {logistic }}\left(f\left(\mathbf{x}_{i}\right), y_{i}\right)+\frac{\lambda}{2}\|f\|_{\mathcal{H}}^{2} \\
& =\underset{f \in \mathcal{H}}{\arg \min } \frac{1}{n} \sum_{i=1}^{n} \ln \left(1+e^{-y_{i} f\left(\mathbf{x}_{i}\right)}\right)+\frac{\lambda}{2}\|f\|_{\mathcal{H}}^{2}
\end{aligned}
$$

- Can be interpreted as a regularized conditional maximum likelihood estimator
- No explicit solution, but smooth convex optimization problem that can be solved numerically

## Solving KLR

- By the representer theorem, any solution of KLR can be expanded as

$$
\hat{f}(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)
$$

and as always we have:

$$
\left(\hat{f}\left(\mathbf{x}_{1}\right), \ldots, \hat{f}\left(\mathbf{x}_{n}\right)\right)^{\top}=\mathbf{K} \boldsymbol{\alpha} \quad \text { and } \quad\|\hat{f}\|_{\mathcal{H}}^{2}=\boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

- To find $\boldsymbol{\alpha}$ we therefore need to solve:

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}} \frac{1}{n} \sum_{i=1}^{n} \ln \left(1+e^{-y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}}\right)+\frac{\lambda}{2} \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

## Technical facts

Sigmoid:

- $\sigma(u)=\frac{1}{1+e^{-u}}$
- $\sigma(-u)=1-\sigma(u)$
- $\sigma^{\prime}(u)=\sigma(u) \sigma(-u) \geq 0$

Logistic loss:

- $\ell_{\text {logistic }}(u)=\ln \left(1+e^{-u}\right)$
- $\ell_{\text {logistic }}^{\prime}(u)=-\sigma(-u)$
- $\ell_{\text {logistic }}^{\prime \prime}(u)=\sigma(u) \sigma(-u) \geq 0$

## Back to KLR

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}} J(\boldsymbol{\alpha})=\frac{1}{n} \sum_{i=1}^{n} \ell_{\text {logistic }}\left(y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}\right)+\frac{\lambda}{2} \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

This is a smooth convex optimization problem, that can be solved by many numerical methods. Let us explicit one of them, Newton's method, which iteratively approximates $J$ by a quadratic function and solves the quadratic problem.
The quadratic approximation near a point $\boldsymbol{\alpha}_{0}$ is the function:
$J_{q}(\boldsymbol{\alpha})=J\left(\boldsymbol{\alpha}_{0}\right)+\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}_{0}\right)^{\top} \nabla J\left(\boldsymbol{\alpha}_{0}\right)+\frac{1}{2}\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}_{0}\right)^{\top} \nabla^{2} J\left(\boldsymbol{\alpha}_{0}\right)\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}_{0}\right)$
Let us compute the different terms...

## Computing the quadratic approximation

$$
\frac{\partial J}{\partial \alpha_{j}}=\frac{1}{n} \sum_{i=1}^{n} \underbrace{\ell_{\text {logistic }}^{\prime}\left(y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}\right)}_{P_{i}(\boldsymbol{\alpha})} y_{i} \mathbf{K}_{i j}+\lambda[\mathbf{K} \boldsymbol{\alpha}]_{j}
$$

therefore

$$
\nabla J(\boldsymbol{\alpha})=\frac{1}{n} \mathbf{K} \mathbf{P}(\boldsymbol{\alpha}) \mathbf{y}+\lambda \mathbf{K} \boldsymbol{\alpha}
$$

where $\mathbf{P}(\boldsymbol{\alpha})=\operatorname{diag}\left(P_{1}(\boldsymbol{\alpha}), \ldots, P_{n}(\boldsymbol{\alpha})\right)$.

$$
\frac{\partial^{2} J}{\partial \alpha_{j} \partial \alpha_{l}}=\frac{1}{n} \sum_{i=1}^{n} \underbrace{\ell_{\text {logistic }}^{\prime \prime}\left(y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}\right)}_{W_{i}(\boldsymbol{\alpha})} y_{i} \mathbf{K}_{i j} y_{i} \mathbf{K}_{i l}+\lambda \mathbf{K}_{j l}
$$

therefore

$$
\nabla^{2} J(\boldsymbol{\alpha})=\frac{1}{n} \mathbf{K W}(\boldsymbol{\alpha}) \mathbf{K}+\lambda \mathbf{K}
$$

where $\mathbf{W}(\boldsymbol{\alpha})=\operatorname{diag}\left(W_{1}(\boldsymbol{\alpha}), \ldots, W_{n}(\boldsymbol{\alpha})\right)$.

## Computing the quadratic approximation

$$
J_{q}(\boldsymbol{\alpha})=J\left(\boldsymbol{\alpha}_{0}\right)+\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}_{0}\right)^{\top} \nabla J\left(\boldsymbol{\alpha}_{0}\right)+\frac{1}{2}\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}_{0}\right)^{\top} \nabla^{2} J\left(\boldsymbol{\alpha}_{0}\right)\left(\boldsymbol{\alpha}-\boldsymbol{\alpha}_{0}\right)
$$

Terms that depend on $\boldsymbol{\alpha}$, with $\mathbf{P}=\mathbf{P}\left(\boldsymbol{\alpha}_{0}\right)$ and $\mathbf{W}=\mathbf{W}\left(\boldsymbol{\alpha}_{0}\right)$ :

- $\boldsymbol{\alpha}^{\top} \nabla J\left(\boldsymbol{\alpha}_{0}\right)=\frac{1}{n} \boldsymbol{\alpha}^{\top} \mathbf{K P y}+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}_{0}$
- $\frac{1}{2} \boldsymbol{\alpha}^{\top} \nabla^{2} J\left(\boldsymbol{\alpha}_{0}\right) \boldsymbol{\alpha}=\frac{1}{2 n} \boldsymbol{\alpha}^{\top} \mathbf{K W K} \boldsymbol{\alpha}+\frac{\lambda}{2} \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}$
- $-\boldsymbol{\alpha}^{\top} \nabla^{2} J\left(\boldsymbol{\alpha}_{0}\right) \boldsymbol{\alpha}_{0}=-\frac{1}{n} \boldsymbol{\alpha}^{\top} \mathbf{K W K} \boldsymbol{\alpha}_{0}-\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}_{0}$

Putting it all together:

$$
\begin{aligned}
2 J_{q}(\boldsymbol{\alpha}) & =-\frac{2}{n} \boldsymbol{\alpha}^{\top} \mathbf{K} \mathbf{W} \underbrace{\left(\mathbf{K} \boldsymbol{\alpha}_{0}-\mathbf{W}^{-1} \mathbf{P y}\right)}_{:=\mathbf{z}}+\frac{1}{n} \boldsymbol{\alpha}^{\top} \mathbf{K} \mathbf{W K} \boldsymbol{\alpha}+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}+C \\
& =\frac{1}{n}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{z})^{\top} \mathbf{W}(\mathbf{K} \boldsymbol{\alpha}-\mathbf{z})+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}+C
\end{aligned}
$$

This is a standard weighted kernel ridge regression (WKRR) problem!

## Solving KLR by IRLS

In summary, one way to solve KLR is to iteratively solve a WKRR problem until convergence:

$$
\boldsymbol{\alpha}^{t+1} \leftarrow \operatorname{solveWKRR}\left(\mathbf{K}, \mathbf{W}^{t}, \mathbf{z}^{t}\right)
$$

where we update $\mathbf{W}^{t}$ and $\mathbf{z}^{t}$ from $\boldsymbol{\alpha}^{t}$ as follows ( for $i=1, \ldots, n$ ):

- $m_{i} \leftarrow\left[\mathbf{K} \boldsymbol{\alpha}^{t}\right]_{i}$
- $P_{i}^{t} \leftarrow \ell_{\text {logistic }}^{\prime}\left(y_{i} m_{i}\right)=-\sigma\left(-y_{i} m_{i}\right)$
- $W_{i}^{t} \leftarrow \ell_{\text {logistic }}^{\prime \prime}\left(y_{i} m_{i}\right)=\sigma\left(m_{i}\right) \sigma\left(-m_{i}\right)$
- $z_{i}^{t} \leftarrow m_{i}-P_{i}^{t} y_{i} / W_{i}^{t}=m_{i}+y_{i} / \sigma\left(y_{i} m_{i}\right)$

This is the kernelized version of the famous iteratively reweighted least-square (IRLS) method to solve the standard linear logistic regression.

## Loss functions for classifications

We already saw two loss functions for binary classification problems

- The $0 / 1$ loss $\ell_{0 / 1}(f(\mathbf{x}), y)=\mathbf{1}(y f(\mathbf{x})<0)$
- The logistic loss $\ell_{\text {logistic }}(f(\mathbf{x}), y)=\ln \left(1+e^{-y f(x)}\right)$

In both cases, the loss is a function of the margin defined as follows

## Definition

In binary classification $(\mathcal{Y}=\{-1,1\})$, the margin of the function $f$ for a pair ( $\mathbf{x}, \mathrm{y}$ ) is:

$$
y f(\mathbf{x}) .
$$

In both cases the loss is a decreasing function of the margin, i.e.,

$$
\ell(f(\mathbf{x}), y)=\varphi(y f(\mathbf{x})), \quad \text { with } \varphi \text { non-increasing }
$$

What about other similar loss functions?

## Loss function examples

| Method | $\varphi(u)$ |
| :---: | :---: |
| Kernel logistic regression | $\log \left(1+e^{-u}\right)$ |
| Support vector machine (1-SVM) | $\max (1-u, 0)$ |
| Support vector machine $(2-$ SVM $)$ | $\max (1-u, 0)^{2}$ |
| Boosting | $e^{-u}$ |

## Large-margin classifiers

## Definition

Given a non-increasing function $\varphi: \mathbb{R} \rightarrow \mathbb{R}_{+}$, a (kernel) large-margin classifier is an algorithm that estimates a function $f: \mathcal{X} \rightarrow \mathbb{R}$ by solving

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} \varphi\left(y_{i} f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2}
$$

Hence, KLR is a large-margin classifier, corresponding to $\varphi(u)=\ln \left(1+e^{-u}\right)$. Many more are possible.

Questions:
(1) Can we solve the optimization problem for other $\varphi$ 's?
(2) Is it a good idea to optimize this objective function, if at the end of the day we are interested in the $\ell_{0 / 1}$ loss, i.e., learning models that make few errors?

## Solving large-margin classifiers

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} \varphi\left(y_{i} f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2}
$$

- By the representer theorem, the solution of the unconstrained problem can be expanded as:

$$
f(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)
$$

- Plugging into the original problem we obtain the following unconstrained and convex optimization problem in $\mathbb{R}^{n}$ :

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}}\left\{\frac{1}{n} \sum_{i=1}^{n} \varphi\left(y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}\right)+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}\right\}
$$

- When $\varphi$ is convex, this can be solved using general tools for convex optimization, or specific algorithms (e.g., for SVM, see later).

## A tiny bit of learning theory

## Assumptions and notations

- Let $\mathbb{P}$ be an (unknown) distribution on $\mathcal{X} \times \mathcal{Y}$, and $\eta(\mathbf{x})=\mathbb{P}(Y=1 \mid X=\mathbf{x})$ a measurable version of the conditional distribution of $Y$ given $X$
- Assume the training set $\mathcal{S}_{n}=\left(X_{i}, Y_{i}\right)_{i=1, \ldots, n}$ are i.i.d. random variables according to $\mathbb{P}$.
- The risk of a classifier $f: \mathcal{X} \rightarrow \mathbb{R}$ is $R(f)=\mathbb{P}(\operatorname{sign}(f(X)) \neq Y)$
- The Bayes risk is

$$
R^{*}=\inf _{f \text { measurable }} R(f)
$$

which is attained for $f^{*}(\mathbf{x})=\eta(\mathbf{x})-1 / 2$

- The empirical risk of a classifier $f: \mathcal{X} \rightarrow \mathbb{R}$ is

$$
R^{n}(f)=\frac{1}{n} \sum_{i=1}^{n} \mathbf{1}\left(\operatorname{sign}\left(f\left(X_{i}\right)\right) \neq Y_{i}\right)
$$

## $\varphi$-risk

- Let the empirical $\varphi$-risk be the empirical risk optimized by a large-margin classifier:

$$
R_{\varphi}^{n}(f)=\frac{1}{n} \sum_{i=1}^{n} \varphi\left(Y_{i} f\left(X_{i}\right)\right)
$$

- It is the empirical version of the $\varphi$-risk

$$
R_{\varphi}(f)=\mathbb{E}[\varphi(Y f(X))]
$$

- Can we hope to have a small risk $R(f)$ if we focus instead on the $\varphi$-risk $R_{\varphi}(f)$ ?

## A small $\varphi$-risk ensures a small $0 / 1$ risk

## Theorem (Bartlett et al., 2003)

Let $\varphi: \mathbb{R} \rightarrow \mathbb{R}_{+}$be convex, non-increasing, differentiable at 0 with $\varphi^{\prime}(0)<0$. Let $f: \mathcal{X} \rightarrow \mathbb{R}$ measurable such that

$$
R_{\varphi}(f)=\min _{g \text { measurable }} R_{\varphi}(g)=R_{\varphi}^{*}
$$

Then

$$
R(f)=\min _{g \text { measurable }} R(g)=R^{*} .
$$

Remarks:

- This tells us that, if we know $\mathbb{P}$, then minimizing the $\varphi$-risk is a good idea even if our focus is on the classification error.
- The assumptions on $\varphi$ can be relaxed; it works for the broader class of classification-calibrated loss functions (Bartlett et al., 2003).
- More generally, we can show that if $R_{\varphi}(f)-R_{\varphi}^{*}$ is small, then $R(f)-R^{*}$ is small too (Bartlett et al., 2003).

## A small $\varphi$-risk ensures a small $0 / 1$ risk

Proof sketch: Show that $f(\mathbf{x})$ is necessarily consistent with $\eta(\mathbf{x})=\mathbb{P}(Y=1 \mid X=\mathbf{x})$, if $f$ minimizes $R_{\varphi}$, and thus minimizes $R$.

Condition on $X=\mathbf{x}$ :

$$
\begin{aligned}
R_{\varphi}(f \mid X=\mathbf{x}) & =\mathbb{E}[\varphi(Y f(X)) \mid X=\mathbf{x}]=\eta(\mathbf{x}) \varphi(f(\mathbf{x}))+(1-\eta(\mathbf{x})) \varphi(-f(\mathbf{x})) \\
R_{\varphi}(-f \mid X=\mathbf{x}) & =\mathbb{E}[\varphi(-Y f(X)) \mid X=\mathbf{x}]=\eta(\mathbf{x}) \varphi(-f(\mathbf{x}))+(1-\eta(\mathbf{x})) \varphi(f(\mathbf{x}))
\end{aligned}
$$

Therefore:

$$
R_{\varphi}(f \mid X=\mathbf{x})-R_{\varphi}(-f \mid X=\mathbf{x})=[2 \eta(\mathbf{x})-1] \times[\varphi(f(\mathbf{x}))-\varphi(-f(\mathbf{x}))]
$$

This must be a.s. $\leq 0$ because $R_{\varphi}(f) \leq R_{\varphi}(-f)$, which implies:

- if $\eta(\mathbf{x})>\frac{1}{2}, \varphi(f(\mathbf{x})) \leq \varphi(-f(\mathbf{x})) \Longrightarrow f(x) \geq 0$
- if $\eta(\mathbf{x})<\frac{1}{2}, \varphi(f(\mathbf{x})) \geq \varphi(-f(\mathbf{x})) \Longrightarrow f(x) \leq 0$

These inequalities are in fact strict thanks to the assumptions we made on $\varphi$ (left as exercice).

## Empirical risk minimization (ERM)

To find a function with a small $\varphi$-risk, the following is a good candidate:

## Definition

The ERM estimator on a functional class $\mathcal{F}$ is the solution (when it exists) of:

$$
\hat{f}_{n}=\underset{f \in \mathcal{F}}{\operatorname{argmin}} R_{\varphi}^{n}(f) .
$$

## Empirical risk minimization (ERM)

To find a function with a small $\varphi$-risk, the following is a good candidate:

## Definition

The ERM estimator on a functional class $\mathcal{F}$ is the solution (when it exists) of:

$$
\hat{f}_{n}=\underset{f \in \mathcal{F}}{\operatorname{argmin}} R_{\varphi}^{n}(f) .
$$

## Questions

- Is $R_{\varphi}^{n}(f)$ a good estimate of the true risk $R_{\varphi}(f)$ ?
- Is $R_{\varphi}\left(\hat{f}_{n}\right)$ small?

## Empirical risk minimization (ERM)

To find a function with a small $\varphi$-risk, the following is a good candidate:

## Definition

The ERM estimator on a functional class $\mathcal{F}$ is the solution (when it exists) of:

$$
\hat{f}_{n}=\underset{f \in \mathcal{F}}{\operatorname{argmin}} R_{\varphi}^{n}(f) .
$$

## Questions

- Is $R_{\varphi}^{n}(f)$ a good estimate of the true risk $R_{\varphi}(f)$ ?
- Is $R_{\varphi}\left(\hat{f}_{n}\right)$ small?

$$
R_{\varphi}\left(\hat{f}_{n}\right)-R_{\varphi}^{\star}=\underbrace{R_{\varphi}\left(\hat{f}_{n}\right)-\inf _{f \in \mathcal{F}} R_{\varphi}(f)}_{\text {estimation error }}+\underbrace{\inf _{f \in \mathcal{F}} R_{\varphi}(f)-R_{\varphi}^{\star}}_{\text {approximation error }} .
$$

## Class capacity

## Motivations

- The ERM principle gives a good solution if $R_{\varphi}\left(\hat{f}_{n}\right)$ is similar to the minimum achievable risk $\inf _{f \in \mathcal{F}} R_{\varphi}(f)$.
- This can be ensured if $\mathcal{F}$ is not "too large".
- We need a measure of the "capacity" of $\mathcal{F}$.

## Definition: Rademacher complexity

The Rademacher complexity of a class of functions $\mathcal{F}$ is:

$$
\operatorname{Rad}_{n}(\mathcal{F})=\mathbb{E}_{X, \sigma}\left[\sup _{f \in \mathcal{F}}\left|\frac{2}{n} \sum_{i=1}^{n} \sigma_{i} f\left(X_{i}\right)\right|\right],
$$

where the expectation is over $\left(X_{i}\right)_{i=1, \ldots, n}$ and the independent uniform $\{ \pm 1\}$-valued (Rademacher) random variables $\left(\sigma_{i}\right)_{i=1, \ldots, n}$.

## Basic learning bounds

## Theorem

Suppose $\varphi$ is Lipschitz with constant $L_{\varphi}$ :

$$
\forall u, u^{\prime} \in \mathbb{R}, \quad\left|\varphi(u)-\varphi\left(u^{\prime}\right)\right| \leq L_{\varphi}\left|u-u^{\prime}\right| .
$$

Then the $\varphi$-risk of the ERM estimator satisfies (on average over the sampling of training set)

$$
\underbrace{\mathbb{E}_{\mathcal{S}_{n}} R_{\varphi}\left(\hat{f}_{n}\right)-R_{\varphi}^{*}}_{\text {Excess } \varphi \text {-risk }} \leq \underbrace{4 L_{\varphi} \operatorname{Rad}_{n}(\mathcal{F})}_{\text {Estimation error }}+\underbrace{\inf _{f \in \mathcal{F}} R_{\varphi}(f)-R_{\varphi}^{*}}_{\text {Approximation error }}
$$

This quantifies a trade-off between:

- $\mathcal{F}$ "large" = overfitting (approximation error small, estimation error large)
- $\mathcal{F}$ "small" $=$ underfitting (estimation error small, approximation error large)

## ERM in RKHS balls

## Principle

- Assume $\mathcal{X}$ is endowed with a p.d. kernel.
- We consider the ball of radius $B$ in the RKHS as function class for the ERM:

$$
\mathcal{F}_{B}=\left\{f \in \mathcal{H}:\|f\|_{\mathcal{H}} \leq B\right\} .
$$

Theorem (capacity control of RKHS balls)

$$
\operatorname{Rad}_{n}\left(\mathcal{F}_{B}\right) \leq \frac{2 B \sqrt{\mathbb{E} K(X, X)}}{\sqrt{n}}
$$

## Proof (1/2)

$$
\begin{aligned}
\operatorname{Rad}_{n}\left(\mathcal{F}_{B}\right) & =\mathbb{E}_{X, \sigma}\left[\sup _{f \in \mathcal{F}_{B}}\left|\frac{2}{n} \sum_{i=1}^{n} \sigma_{i} f\left(X_{i}\right)\right|\right] \\
& =\mathbb{E}_{X, \sigma}\left[\sup _{f \in \mathcal{F}_{B}}\left|\left\langle f, \frac{2}{n} \sum_{i=1}^{n} \sigma_{i} K_{X_{i}}\right\rangle\right|\right] \quad(\text { RKHS ) } \\
& =\mathbb{E}_{X, \sigma}\left[B\left\|\frac{2}{n} \sum_{i=1}^{n} \sigma_{i} K_{X_{i}}\right\|_{\mathcal{H}}\right] \quad \text { (Cauchy-Schwarz) } \\
& =\frac{2 B}{n} \mathbb{E}_{X, \sigma}\left[\sqrt{\left.\left\|\sum_{i=1}^{n} \sigma_{i} K_{X_{i}}\right\|_{\mathcal{H}}^{2}\right]}\right. \\
& \leq \frac{2 B}{n} \sqrt{\mathbb{E}_{X, \sigma}\left[\sum_{i, j=1}^{n} \sigma_{i} \sigma_{j} K\left(X_{i}, X_{j}\right)\right]} \text { (Jensen) }
\end{aligned}
$$

## Proof (2/2)

But $\mathbb{E}_{\sigma}\left[\sigma_{i} \sigma_{j}\right]$ is 1 if $i=j, 0$ otherwise. Therefore:

$$
\begin{aligned}
\operatorname{Rad}_{n}\left(\mathcal{F}_{B}\right) & \leq \frac{2 B}{n} \sqrt{\mathbb{E}_{X}\left[\sum_{i, j=1}^{n} \mathbb{E}_{\sigma}\left[\sigma_{i} \sigma_{j}\right] K\left(X_{i}, X_{j}\right)\right]} \\
& \leq \frac{2 B}{n} \sqrt{\mathbb{E}_{X} \sum_{i=1}^{n} K\left(X_{i}, X_{i}\right)} \\
& =\frac{2 B \sqrt{\mathbb{E}_{X} K(X, X)}}{\sqrt{n}}
\end{aligned}
$$

## Basic learning bounds in RKHS balls

## Corollary

Suppose $K(X, X) \leq \kappa^{2}$ a.s. (e.g., Gaussian kernel and $\kappa=1$ ). Then the ERM estimator in $\mathcal{F}_{B}$ satisfies

$$
\mathbb{E} R_{\varphi}\left(\hat{f}_{n}\right)-R_{\varphi}^{*} \leq \frac{8 L_{\varphi} \kappa B}{\sqrt{n}}+\left[\inf _{f \in \mathcal{F}_{B}} R_{\varphi}(f)-R_{\varphi}^{*}\right]
$$

## Remarks

- B controls the trade-off between approximation and estimation error
- The bound on expression error is independent of $\mathcal{P}$ and decreases with $n$
- The approximation error is harder to analyze in general
- In practice, $B$ (or $\lambda$, next slide) is tuned by cross-validation

## ERM as penalized risk minimization

- ERM over $\mathcal{F}_{B}$ solves the constrained minimization problem:

$$
\left\{\begin{array}{l}
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} \varphi\left(y_{i} f\left(\mathbf{x}_{i}\right)\right) \\
\text { subject to }\|f\|_{\mathcal{H}} \leq B
\end{array}\right.
$$

- To make this practical we assume that $\varphi$ is convex.
- The problem is then a convex problem in $f$ for which strong duality holds. In particular $f$ solves the problem if and only if it solves for some dual parameter $\lambda$ the unconstrained problem:

$$
\min _{f \in \mathcal{H}}\left\{\frac{1}{n} \sum_{i=1}^{n} \varphi\left(y_{i} f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2}\right\} .
$$

## Summary: large margin classifiers

- $\varphi$ calibrated (e.g., decreasing, $\left.\varphi^{\prime}(0)<0\right) \Longrightarrow$ good proxy for classification error
- $\varphi$ convex + representer theorem $\Longrightarrow$ efficient algorithms

## A few slides on convex duality

## Strong Duality

- Strong duality means that $\max _{\boldsymbol{\nu}} q(\boldsymbol{\nu})=\min _{\mathrm{x}} f(\mathbf{x})$
- Strong duality holds in most "reasonable cases" for convex optimization (to be detailed soon).

## A few slides on convex duality

## Strong Duality

- The relation between $\mathbf{x}^{\star}$ and $\boldsymbol{\nu}^{\star}$ is not always known a priori.

## A few slides on convex duality

Parenthesis on duality gaps

- The duality gap guarantees us that $0 \leq f(\tilde{\mathbf{x}})-f\left(\mathbf{x}^{\star}\right) \leq \delta(\tilde{\mathbf{x}}, \tilde{\nu})$.
- Dual problems are often obtained by Lagrangian or Fenchel duality.

## A few slides on Lagrangian duality

## Setting

- We consider an equality and inequality constrained optimization problem over a variable $\mathbf{x} \in \mathcal{X}$ :

$$
\begin{aligned}
\operatorname{minimize} & f(\mathbf{x}) \\
\text { subject to } & h_{i}(\mathbf{x})=0, \quad i=1, \ldots, m \\
& g_{j}(\mathbf{x}) \leq 0, \quad j=1, \ldots, r
\end{aligned}
$$

making no assumption of $f, g$ and $h$.

- Let us denote by $f^{\star}$ the optimal value of the decision function under the constraints, i.e., $f^{\star}=f\left(\mathbf{x}^{\star}\right)$ if the minimum is reached at a global minimum $\mathbf{x}^{\star}$.

## A few slides on Lagrangian duality

## Lagrangian

The Lagrangian of this problem is the function $L: \mathcal{X} \times \mathbb{R}^{m} \times \mathbb{R}^{r} \rightarrow \mathbb{R}$ defined by:

$$
L(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu})=f(\mathbf{x})+\sum_{i=1}^{m} \lambda_{i} h_{i}(\mathbf{x})+\sum_{j=1}^{r} \mu_{j} g_{j}(\mathbf{x})
$$

## Lagrangian dual function

The Lagrange dual function $g: \mathbb{R}^{m} \times \mathbb{R}^{r} \rightarrow \mathbb{R}$ is:

$$
\begin{aligned}
q(\boldsymbol{\lambda}, \boldsymbol{\mu}) & =\inf _{\mathbf{x} \in \mathcal{X}} L(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu}) \\
& =\inf _{\mathbf{x} \in \mathcal{X}}\left(f(\mathbf{x})+\sum_{i=1}^{m} \lambda_{i} h_{i}(\mathbf{x})+\sum_{j=1}^{r} \mu_{j} g_{j}(\mathbf{x})\right) .
\end{aligned}
$$

## A few slides on convex Lagrangian duality

For the (primal) problem:

$$
\begin{aligned}
\operatorname{minimize} & f(\mathbf{x}) \\
\text { subject to } & h(\mathbf{x})=0, \quad g(\mathbf{x}) \leq 0
\end{aligned}
$$

the Lagrange dual problem is:

$$
\begin{aligned}
\operatorname{maximize} & q(\boldsymbol{\lambda}, \boldsymbol{\mu}) \\
\text { subject to } & \boldsymbol{\mu} \geq 0,
\end{aligned}
$$

## Proposition

- $q$ is concave in $(\boldsymbol{\lambda}, \boldsymbol{\mu})$, even if the original problem is not convex.
- The dual function yields lower bounds on the optimal value $f^{\star}$ of the original problem when $\boldsymbol{\mu}$ is nonnegative:

$$
q(\boldsymbol{\lambda}, \boldsymbol{\mu}) \leq f^{\star}, \quad \forall \boldsymbol{\lambda} \in \mathbb{R}^{m}, \forall \boldsymbol{\mu} \in \mathbb{R}^{r}, \boldsymbol{\mu} \geq 0
$$

## Proofs

- Remember that

$$
L(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu})=f(\mathbf{x})+\sum_{i=1}^{m} \lambda_{i} h_{i}(\mathbf{x})+\sum_{j=1}^{r} \mu_{j} g_{j}(\mathbf{x})
$$

- For each $\mathbf{x}$, the function $(\boldsymbol{\lambda}, \boldsymbol{\mu}) \mapsto L(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu})$ is linear, and therefore both convex and concave in $(\boldsymbol{\lambda}, \boldsymbol{\mu})$. The pointwise minimum of concave functions is concave, therefore $q$ is concave.
- Let $\overline{\mathrm{x}}$ be any feasible point, i.e., $h(\overline{\mathrm{x}})=0$ and $g(\overline{\mathrm{x}}) \leq 0$. Then we have, for any $\boldsymbol{\lambda}$ and $\boldsymbol{\mu} \geq 0$ :

$$
\begin{gathered}
\sum_{i=1}^{m} \lambda_{i} h_{i}(\overline{\mathbf{x}})+\sum_{i=1}^{r} \mu_{i} g_{i}(\overline{\mathbf{x}}) \leq 0 \\
\Longrightarrow \quad L(\overline{\mathbf{x}}, \boldsymbol{\lambda}, \boldsymbol{\mu})=f(\overline{\mathbf{x}})+\sum_{i=1}^{m} \lambda_{i} h_{i}(\overline{\mathbf{x}})+\sum_{i=1}^{r} \mu_{i} g_{i}(\overline{\mathbf{x}}) \leq f(\overline{\mathbf{x}}) \\
\Longrightarrow \quad q(\boldsymbol{\lambda}, \boldsymbol{\mu})=\inf _{\mathbf{x}} L(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu}) \leq L(\overline{\mathbf{x}}, \boldsymbol{\lambda}, \boldsymbol{\mu}) \leq f(\overline{\mathbf{x}}), \quad \forall \overline{\mathbf{x}} .
\end{gathered}
$$

## Weak duality

- Let $q^{*}$ the optimal value of the Lagrange dual problem. Each $q(\boldsymbol{\lambda}, \boldsymbol{\mu})$ is a lower bound for $f^{\star}$ and by definition $q^{\star}$ is the best lower bound that is obtained. The following weak duality inequality therefore always hold:

$$
q^{\star} \leq f^{\star}
$$

- This inequality holds when $q^{\star}$ or $f^{\star}$ are infinite. The difference $q^{\star}-f^{\star}$ is called the optimal duality gap of the original problem.

## Strong duality

- We say that strong duality holds if the optimal duality gap is zero, i.e.:

$$
q^{\star}=f^{\star} .
$$

- If strong duality holds, then the best lower bound that can be obtained from the Lagrange dual function is tight
- Strong duality does not hold for general nonlinear problems.
- It usually holds for convex problems.
- Conditions that ensure strong duality for convex problems are called constraint qualification.
- in that case, we have for all feasible primal and dual points $\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu}$,

$$
q(\boldsymbol{\lambda}, \boldsymbol{\mu}) \leq q\left(\boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right)=L\left(\mathbf{x}^{\star}, \boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right)=f\left(\mathbf{x}^{\star}\right) \leq f(\mathbf{x}) .
$$

## Slater's constraint qualification

Strong duality holds for a convex problem:

$$
\begin{aligned}
\operatorname{minimize} & f(\mathbf{x}) \\
\text { subject to } & g_{j}(\mathbf{x}) \leq 0, \quad j=1, \ldots, r, \\
& \mathbf{A x}=\mathbf{b}
\end{aligned}
$$

if it is strictly feasible, i.e., there exists at least one feasible point that satisfies:

$$
g_{j}(\mathbf{x})<0, \quad j=1, \ldots, r, \quad \mathbf{A x}=\mathbf{b}
$$

## Remarks

- Slater's conditions also ensure that the maximum $q^{\star}($ if $>-\infty)$ is attained, i.e., there exists a point $\left(\boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right)$ with

$$
q\left(\boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right)=q^{\star}=f^{\star}
$$

- They can be sharpened. For example, strict feasibility is not required for affine constraints.
- There exist many other types of constraint qualifications

## Dual optimal pairs

Suppose that strong duality holds, $\mathbf{x}^{\star}$ is primal optimal, $\left(\boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right)$ is dual optimal. Then we have:

$$
\begin{aligned}
f\left(\mathbf{x}^{\star}\right) & =q\left(\boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right) \\
& =\inf _{\mathbf{x} \in \mathbb{R}^{n}}\left\{f(\mathbf{x})+\sum_{i=1}^{m} \lambda_{i}^{\star} h_{i}(\mathbf{x})+\sum_{j=1}^{r} \mu_{j}^{\star} g_{j}(\mathbf{x})\right\} \\
& \leq f\left(\mathbf{x}^{\star}\right)+\sum_{i=1}^{m} \lambda_{i}^{\star} h_{i}\left(\mathbf{x}^{\star}\right)+\sum_{j=1}^{r} \mu_{j}^{\star} g_{j}\left(\mathbf{x}^{\star}\right) \\
& \leq f\left(\mathbf{x}^{\star}\right)
\end{aligned}
$$

Hence both inequalities are in fact equalities.

## Complimentary slackness

The first equality shows that:

$$
L\left(\mathbf{x}^{\star}, \boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right)=\inf _{\mathbf{x} \in \mathbb{R}^{n}} L\left(\mathbf{x}, \boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right),
$$

showing that $\mathbf{x}^{\star}$ minimizes the Lagrangian at $\left(\boldsymbol{\lambda}^{\star}, \boldsymbol{\mu}^{\star}\right)$. The second equality shows the following important property:

## Complimentary slackness

Each optimal Lagrange multiplier is zero unless the corresponding constraint is active at the optimum:

$$
\mu_{j} g_{j}\left(\mathbf{x}^{\star}\right)=0, \quad j=1, \ldots, r
$$

## Outline

(1) Kernel tricks

- Large-margin classifiers
- Interlude: convex optimization and duality
- Support vector machines
(3) Kernel Methods: Unsupervised Learning

4 The Kernel Jungle
(5) Characterizing probabilities with kernels
(6) Open Problems and Research Topics

## Support vector machines (SVM)

- Historically the first "kernel method" for pattern recognition, still the most popular.
- Often state-of-the-art in performance.
- One particular choice of loss function (hinge loss).
- Leads to a sparse solution, i.e., not all points are involved in the decomposition (compression).
- Particular algorithm for fast optimization (decomposition by chunking methods).

## Support vector machines (SVM)

## Definition

- The hinge loss is the function $\mathbb{R} \rightarrow \mathbb{R}_{+}$:

$$
\varphi_{\text {hinge }}(u)=\max (1-u, 0)= \begin{cases}0 & \text { if } u \geq 1 \\ 1-u & \text { otherwise }\end{cases}
$$

- SVM is the corresponding large-margin classifier, which solves:

$$
\min _{f \in \mathcal{H}}\left\{\frac{1}{n} \sum_{i=1}^{n} \varphi_{\text {hinge }}\left(y_{i} f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2}\right\} .
$$

## Problem reformulation $(1 / 3)$

- By the representer theorem, the solution satisfies

$$
\hat{f}(\mathbf{x})=\sum_{i=1}^{n} \hat{\alpha}_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)
$$

where $\hat{\boldsymbol{\alpha}}$ solves

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}}\left\{\frac{1}{n} \sum_{i=1}^{n} \varphi_{\text {hinge }}\left(y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}\right)+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}\right\}
$$

- This is a convex optimization problem
- But the objective function is not smooth (because of the hinge loss)

## Problem reformulation $(2 / 3)$

- Let us introduce additional slack variables $\xi_{1}, \ldots, \xi_{n} \in \mathbb{R}$. The problem is equivalent to:

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\xi} \in \mathbb{R}^{n}}\left\{\frac{1}{n} \sum_{i=1}^{n} \xi_{i}+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}\right\}
$$

subject to:

$$
\xi_{i} \geq \varphi_{\text {hinge }}\left(y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}\right)
$$

- The objective function is now smooth, but not the constraints
- However it is easy to replace the non-smooth constraint by a cunjunction of two smooth constraints, because:

$$
u \geq \varphi_{\text {hinge }}(v) \Leftrightarrow \begin{cases}u & \geq 1-v \\ u & \geq 0\end{cases}
$$

## Problem reformulation (3/3)

In summary, the SVM solution is

$$
\hat{f}(\mathbf{x})=\sum_{i=1}^{n} \hat{\alpha}_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)
$$

where $\hat{\boldsymbol{\alpha}}$ solves:

## SVM (primal formulation)

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\xi} \in \mathbb{R}^{n}} \frac{1}{n} \sum_{i=1}^{n} \xi_{i}+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

subject to:

$$
\begin{cases}y_{i}[\mathbf{K} \alpha]_{i}+\xi_{i}-1 \geq 0, & \text { for } i=1, \ldots, n \\ \xi_{i} \geq 0, & \text { for } i=1, \ldots, n\end{cases}
$$

## Solving the SVM problem

- This is a classical quadratic program (minimization of a convex quadratic function with linear constraints) for which any out-of-the-box optimization package can be used.
- The dimension of the problem and the number of constraints, however, are $2 n$ where $n$ is the number of points. General-purpose QP solvers will have difficulties when $n$ exceeds a few thousands.
- Solving the dual of this problem (also a QP) will be more convenient and lead to faster algorithms (due to the sparsity of the final solution).

## Lagrangian

- Let us introduce the Lagrange multipliers $\boldsymbol{\mu} \in \mathbb{R}^{n}$ and $\boldsymbol{\nu} \in \mathbb{R}^{n}$.
- The Lagrangian of the problem is:

$$
\begin{aligned}
L(\boldsymbol{\alpha}, \boldsymbol{\xi}, \boldsymbol{\mu}, \boldsymbol{\nu})=\frac{1}{n} \sum_{i=1}^{n} & \xi_{i}+\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha} \\
& -\sum_{i=1}^{n} \mu_{i}\left[y_{i}[\mathbf{K} \boldsymbol{\alpha}]_{i}+\xi_{i}-1\right]-\sum_{i=1}^{n} \nu_{i} \xi_{i}
\end{aligned}
$$

or, in matrix notations:

$$
\begin{aligned}
L(\boldsymbol{\alpha}, \boldsymbol{\xi}, \boldsymbol{\mu}, \boldsymbol{\nu})=\boldsymbol{\xi}^{\top} \frac{\mathbf{1}}{n} & +\lambda \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha} \\
& \quad-(\operatorname{diag}(\mathbf{y}) \boldsymbol{\mu})^{\top} \mathbf{K} \boldsymbol{\alpha}-(\boldsymbol{\mu}+\boldsymbol{\nu})^{\top} \boldsymbol{\xi}+\boldsymbol{\mu}^{\top} \mathbf{1}
\end{aligned}
$$

## Minimizing $L(\boldsymbol{\alpha}, \boldsymbol{\xi}, \boldsymbol{\mu}, \boldsymbol{\nu})$ w.r.t. $\boldsymbol{\alpha}$

- $L(\boldsymbol{\alpha}, \boldsymbol{\xi}, \boldsymbol{\mu}, \boldsymbol{\nu})$ is a convex quadratic function in $\boldsymbol{\alpha}$. It is minimized whenever its gradient is null:

$$
\nabla_{\boldsymbol{\alpha}} L=2 \lambda \mathbf{K} \boldsymbol{\alpha}-\mathbf{K} \operatorname{diag}(\mathbf{y}) \boldsymbol{\mu}=\mathbf{K}(2 \lambda \boldsymbol{\alpha}-\operatorname{diag}(\mathbf{y}) \boldsymbol{\mu})
$$

- The following solves $\nabla_{\boldsymbol{\alpha}} L=0$ :

$$
\boldsymbol{\alpha}^{*}=\frac{\operatorname{diag}(\mathbf{y}) \boldsymbol{\mu}}{2 \lambda}
$$

## Minimizing $L(\boldsymbol{\alpha}, \boldsymbol{\xi}, \boldsymbol{\mu}, \boldsymbol{\nu})$ w.r.t. $\boldsymbol{\xi}$

- $L(\boldsymbol{\alpha}, \boldsymbol{\xi}, \boldsymbol{\mu}, \boldsymbol{\nu})$ is a linear function in $\boldsymbol{\xi}$.
- Its minimum is $-\infty$ except when it is constant, i.e., when:

$$
\nabla_{\boldsymbol{\xi}} L=\frac{\mathbf{1}}{n}-\boldsymbol{\mu}-\boldsymbol{\nu}=0
$$

or equivalently

$$
\mu+\nu=\frac{1}{n}
$$

## Dual function

- We therefore obtain the Lagrange dual function:

$$
\begin{aligned}
q(\boldsymbol{\mu}, \boldsymbol{\nu}) & =\inf _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\xi} \in \mathbb{R}^{n}} L(\boldsymbol{\alpha}, \boldsymbol{\xi}, \boldsymbol{\mu}, \boldsymbol{\nu}) \\
& = \begin{cases}\boldsymbol{\mu}^{\top} \mathbf{1}-\frac{1}{4 \lambda} \boldsymbol{\mu}^{\top} \operatorname{diag}(\mathbf{y}) \mathbf{K} \operatorname{diag}(\mathbf{y}) \boldsymbol{\mu} & \text { if } \boldsymbol{\mu}+\boldsymbol{\nu}=\frac{\mathbf{1}}{n} \\
-\infty & \text { otherwise }\end{cases}
\end{aligned}
$$

- The dual problem is:

$$
\begin{aligned}
\operatorname{maximize} & q(\boldsymbol{\mu}, \boldsymbol{\nu}) \\
\text { subject to } & \boldsymbol{\mu} \geq 0, \boldsymbol{\nu} \geq 0
\end{aligned}
$$

## Dual problem

- If $\mu_{i}>1 / n$ for some $i$, then there is no $\nu_{i} \geq 0$ such that $\mu_{i}+\nu_{i}=1 / n$, hence $q(\boldsymbol{\mu}, \boldsymbol{\nu})=-\infty$.
- If $0 \leq \mu_{i} \leq 1 / n$ for all $i$, then the dual function takes finite values that depend only on $\mu$ by taking $\nu_{i}=1 / n-\mu_{i}$.
- The dual problem is therefore equivalent to:

$$
\max _{0 \leq \boldsymbol{\mu} \leq \mathbf{1} / n} \boldsymbol{\mu}^{\top} \mathbf{1}-\frac{1}{4 \lambda} \boldsymbol{\mu}^{\top} \operatorname{diag}(\mathbf{y}) \mathbf{K} \operatorname{diag}(\mathbf{y}) \boldsymbol{\mu}
$$

or with indices:

$$
\max _{0 \leq \boldsymbol{\mu} \leq 1 / n} \sum_{i=1}^{n} \mu_{i}-\frac{1}{4 \lambda} \sum_{i, j=1}^{n} y_{i} y_{j} \mu_{i} \mu_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)
$$

## Back to the primal

- Once the dual problem is solved in $\boldsymbol{\mu}$ we get a solution of the primal problem by $\boldsymbol{\alpha}=\operatorname{diag}(\mathbf{y}) \boldsymbol{\mu} / 2 \lambda$.
- Because the link is so simple, we can therefore directly plug this into the dual problem to obtain the QP that $\boldsymbol{\alpha}$ must solve:

## SVM (dual formulation)

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}} 2 \sum_{i=1}^{n} \alpha_{i} y_{i}-\sum_{i, j=1}^{n} \alpha_{i} \alpha_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)=2 \boldsymbol{\alpha}^{\top} \mathbf{y}-\boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}
$$

subject to:

$$
0 \leq y_{i} \alpha_{i} \leq \frac{1}{2 \lambda n}, \quad \text { for } i=1, \ldots, n
$$

## Complimentary slackness conditions

- The complimentary slackness conditions are, for $i=1, \ldots, n$ :

$$
\left\{\begin{array}{l}
\mu_{i}\left[y_{i} f\left(\mathbf{x}_{i}\right)+\xi_{i}-1\right]=0 \\
\nu_{i} \xi_{i}=0
\end{array}\right.
$$

- In terms of $\alpha$ this can be rewritten as:

$$
\left\{\begin{array}{l}
\alpha_{i}\left[y_{i} f\left(\mathbf{x}_{i}\right)+\xi_{i}-1\right]=0 \\
\left(\alpha_{i}-\frac{y_{i}}{2 \lambda n}\right) \xi_{i}=0
\end{array}\right.
$$

## Analysis of KKT conditions

$$
\left\{\begin{array}{l}
\alpha_{i}\left[y_{i} f\left(\mathbf{x}_{i}\right)+\xi_{i}-1\right]=0, \\
\left(\alpha_{i}-\frac{y_{i}}{2 \lambda n}\right) \xi_{i}=0 .
\end{array}\right.
$$

- If $\alpha_{i}=0$, then the second constraint is active: $\xi_{i}=0$. This implies $y_{i} f\left(\mathbf{x}_{i}\right) \geq 1$.
- If $0<y_{i} \alpha_{i}<\frac{1}{2 \lambda n}$, then both constraints are active: $\xi_{i}=0$ et $y_{i} f\left(\mathbf{x}_{i}\right)+\xi_{i}-1=0$. This implies $y_{i} f\left(\mathbf{x}_{i}\right)=1$.
- If $\alpha_{i}=\frac{y_{i}}{2 \lambda n}$, then the second constraint is not active $\left(\xi_{i} \geq 0\right)$ while the first one is active: $y_{i} f\left(\mathbf{x}_{i}\right)+\xi_{i}=1$. This implies $y_{i} f\left(\mathbf{x}_{i}\right) \leq 1$

## Another point of view without KKT

The dual can be rewritten as the minimization of a quadratic function under box constraints

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}}\left\{q(\boldsymbol{\alpha})=\frac{1}{2} \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}-\boldsymbol{\alpha}^{\top} \mathbf{y}\right\} \quad \text { s.t. } \quad \forall i, \quad 0 \leq y_{i} \alpha_{i} \leq C
$$

The gradient is $\nabla q(\boldsymbol{\alpha})=\mathbf{K} \boldsymbol{\alpha}-\mathbf{y}=\left[f\left(\mathbf{x}_{i}\right)-y_{i}\right]_{i=1, \ldots, n}$.
Assume $y_{i}=1$ (case with $y_{i}=-1$ is similar) and consider three cases:

- Case 1: $0<y_{i} \boldsymbol{\alpha}_{i}^{\star}<C$;
- $\left[\nabla q\left(\boldsymbol{\alpha}^{\star}\right)\right]_{i}=0$;
- $\Rightarrow y_{i} f\left(x_{i}\right)=1$.

## Another point of view without KKT

The dual can be rewritten as the minimization of a quadratic function under box constraints

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}}\left\{q(\boldsymbol{\alpha})=\frac{1}{2} \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}-\boldsymbol{\alpha}^{\top} \mathbf{y}\right\} \quad \text { s.t. } \quad \forall i, \quad 0 \leq y_{i} \alpha_{i} \leq C
$$

The gradient is $\nabla q(\boldsymbol{\alpha})=\mathbf{K} \boldsymbol{\alpha}-\mathbf{y}=\left[f\left(\mathbf{x}_{i}\right)-y_{i}\right]_{i=1, \ldots, n}$.
Assume $y_{i}=1$ (case with $y_{i}=-1$ is similar) and consider three cases:

- Case 2: $y_{i} \boldsymbol{\alpha}_{i}^{\star}=C$;
- $\left[\nabla q\left(\boldsymbol{\alpha}^{\star}\right)\right]_{i} \leq 0$;
- $\Rightarrow y_{i} f\left(\mathbf{x}_{i}\right) \leq 1$.

## Another point of view without KKT

The dual can be rewritten as the minimization of a quadratic function under box constraints

$$
\min _{\boldsymbol{\alpha} \in \mathbb{R}^{n}}\left\{q(\boldsymbol{\alpha})=\frac{1}{2} \boldsymbol{\alpha}^{\top} \mathbf{K} \boldsymbol{\alpha}-\boldsymbol{\alpha}^{\top} \mathbf{y}\right\} \quad \text { s.t. } \quad \forall i, \quad 0 \leq y_{i} \alpha_{i} \leq C
$$

The gradient is $\nabla q(\boldsymbol{\alpha})=\mathbf{K} \boldsymbol{\alpha}-\mathbf{y}=\left[f\left(\mathbf{x}_{i}\right)-y_{i}\right]_{i=1, \ldots, n}$.
Assume $y_{i}=1$ (case with $y_{i}=-1$ is similar) and consider three cases:

- Case 3: $\boldsymbol{\alpha}_{i}^{\star}=0$;
- $\left[\nabla q\left(\boldsymbol{\alpha}^{\star}\right)\right]_{i} \geq 0$;
- $\Rightarrow y_{i} f\left(\mathbf{x}_{i}\right) \geq 1$.

## Geometric interpretation

## Geometric interpretation

## Geometric interpretation

## Support vectors

## Consequence of KKT conditions

- The training points with $\alpha_{i} \neq 0$ are called support vectors.
- Only support vectors are important for the classification of new points:

$$
\forall \mathbf{x} \in \mathcal{X}, \quad f(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)=\sum_{i \in S V} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right)
$$

where $S V$ is the set of support vectors.

## Consequences

- The solution is sparse in $\boldsymbol{\alpha}$, leading to fast algorithms for training (use of decomposition methods).
- The classification of a new point only involves kernel evaluations with support vectors (fast).

## Remark: C-SVM

- Often the SVM optimization problem is written in terms of a regularization parameter $C$ instead of $\lambda$ as follows:

$$
\underset{f \in \mathcal{H}}{\arg \min } \frac{1}{2}\|f\|_{\mathcal{H}}^{2}+C \sum_{i=1}^{n} L_{\text {hinge }}\left(f\left(\mathbf{x}_{i}\right), y_{i}\right) .
$$

- This is equivalent to our formulation with $C=\frac{1}{2 n \lambda}$.
- The SVM optimization problem is then:

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{d}} 2 \sum_{i=1}^{n} \alpha_{i} y_{i}-\sum_{i, j=1}^{n} \alpha_{i} \alpha_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)
$$

subject to:

$$
0 \leq y_{i} \alpha_{i} \leq C, \quad \text { for } i=1, \ldots, n
$$

- This formulation is often called C-SVM.

## Remark: 2-SVM

- A variant of the SVM, sometimes called 2-SVM, is obtained by replacing the hinge loss by the square hinge loss:

$$
\min _{f \in \mathcal{H}}\left\{\frac{1}{n} \sum_{i=1}^{n} \varphi_{\text {hinge }}\left(y_{i} f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda\|f\|_{\mathcal{H}}^{2}\right\} .
$$

- After some computation (left as exercice) we find that the dual problem of the 2-SVM is:

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{d}} 2 \boldsymbol{\alpha}^{\top} \mathbf{y}-\boldsymbol{\alpha}^{\top}(\mathbf{K}+n \lambda I) \boldsymbol{\alpha}
$$

subject to:

$$
0 \leq y_{i} \alpha_{i}, \quad \text { for } i=1, \ldots, n .
$$

- This is therefore equivalent to the previous SVM with the kernel $\mathrm{K}+n \lambda /$ and $C=+\infty$

## Principal Component Analysis (PCA)

## Classical setting

- Let $\mathcal{S}=\left\{\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right\}$ be a set of vectors $\left(\mathbf{x}_{i} \in \mathbb{R}^{d}\right)$
- PCA is a classical algorithm in multivariate statistics to define a set of orthogonal directions that capture the maximum variance
- Applications: low-dimensional representation of high-dimensional points, visualization

## Principal Component Analysis (PCA)

## Formalization

- Assume that the data are centered (otherwise center them as preprocessing), i.e.:

$$
\frac{1}{n} \sum_{i=1}^{n} \mathbf{x}_{i}=0
$$

- The orthogonal projection onto a direction $\mathbf{w} \in \mathbb{R}^{d}$ is the function $h_{\mathrm{w}}: \mathbb{R}^{d} \rightarrow \mathbb{R}$ defined by:

$$
h_{\mathbf{w}}(\mathbf{x})=\mathbf{x}^{\top} \frac{\mathbf{w}}{\|\mathbf{w}\|}
$$

## Principal Component Analysis (PCA)

## Formalization

- The empirical variance captured by $h_{\mathbf{w}}$ is:

$$
\operatorname{vâr}\left(h_{\mathbf{w}}\right):=\frac{1}{n} \sum_{i=1}^{n} h_{\mathbf{w}}\left(\mathbf{x}_{i}\right)^{2}=\frac{1}{n} \sum_{i=1}^{n} \frac{\left(\mathbf{x}_{i}^{\top} \mathbf{w}\right)^{2}}{\|\mathbf{w}\|^{2}} .
$$

- The $i$-th principal direction $\mathbf{w}_{i}(i=1, \ldots, d)$ is defined by:

$$
\mathbf{w}_{i}=\underset{\mathbf{w} \perp\left\{\mathbf{w}_{1}, \ldots, \mathbf{w}_{i-1}\right\}}{\arg \max } \operatorname{var}\left(h_{\mathbf{w}}\right) \text { s.t. }\|\mathbf{w}\|=1 .
$$

## Principal Component Analysis (PCA)

## Solution

- Let $\mathbf{X}$ be the $n \times d$ data matrix whose rows are the vectors $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$. We can then write:

$$
\operatorname{vâr}\left(h_{\mathbf{w}}\right)=\frac{1}{n} \sum_{i=1}^{n} \frac{\left(\mathbf{x}_{i}^{\top} \mathbf{w}\right)^{2}}{\|\mathbf{w}\|^{2}}=\frac{1}{n} \frac{\mathbf{w}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}}{\mathbf{w}^{\top} \mathbf{w}}
$$

- The solutions of:

$$
\mathbf{w}_{i}=\underset{\mathbf{w} \perp\left\{\mathbf{w}_{1}, \ldots, \mathbf{w}_{i-1}\right\}}{\arg \max } \mathbf{w}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w} \text { s.t. }\|\mathbf{w}\|=1
$$

## Principal Component Analysis (PCA)

## Solution

- Let $\mathbf{X}$ be the $n \times d$ data matrix whose rows are the vectors $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$. We can then write:

$$
\operatorname{vâr}\left(h_{\mathbf{w}}\right)=\frac{1}{n} \sum_{i=1}^{n} \frac{\left(\mathbf{x}_{i}^{\top} \mathbf{w}\right)^{2}}{\|\mathbf{w}\|^{2}}=\frac{1}{n} \frac{\mathbf{w}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}}{\mathbf{w}^{\top} \mathbf{w}} .
$$

- The solutions of:

$$
\mathbf{w}_{i}=\underset{\mathbf{w} \perp\left\{\mathbf{w}_{1}, \ldots, \mathbf{w}_{i-1}\right\}}{\arg \max } \mathbf{w}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w} \text { s.t. }\|\mathbf{w}\|=1
$$

are the successive eigenvectors of $\mathbf{X}^{\top} \mathbf{X}$, ranked by decreasing eigenvalues.

## Kernel Principal Component Analysis (PCA)

Let $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ be a set of data points in $\mathcal{X}$; let $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ be a positive definite kernel and $\mathcal{H}$ be its RKHS.

## Formalization

- Assume that the data are centered (otherwise center by manipulating the kernel matrix), i.e.:

$$
\frac{1}{n} \sum_{i=1}^{n} \mathrm{x}_{i} \quad \Longrightarrow \frac{1}{n} \sum_{i=1}^{n} \varphi\left(\mathrm{x}_{i}\right)=0
$$

- The orthogonal projection onto a direction $f \in \mathcal{H}$ is the function $h_{f}: \mathcal{X} \rightarrow \mathbb{R}$ defined by:

$$
h_{\mathrm{w}}(\mathbf{x})=\mathrm{x}^{\top} \frac{\mathrm{w}}{\|\mathbf{w}\|} \quad \Longrightarrow \quad h_{f}(\mathbf{x})=\left\langle\varphi(\mathbf{x}), \frac{f}{\|f\|_{\mathcal{H}}}\right\rangle_{\mathcal{H}}
$$

## Kernel Principal Component Analysis (PCA)

Let $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ be a set of data points in $\mathcal{X}$; let $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ be a positive definite kernel and $\mathcal{H}$ be its RKHS.

## Formalization

- The empirical variance captured by $h_{f}$ is:

$$
\operatorname{vâr}\left(h_{\mathbf{w}}\right)=\frac{1}{n} \sum_{i=1}^{n} \frac{\left(\mathbf{x}_{i}^{\top} \mathbf{w}\right)^{2}}{\|\mathbf{w}\|^{2}} \Longrightarrow \quad \operatorname{vâr}\left(h_{f}\right):=\frac{1}{n} \sum_{i=1}^{n} \frac{\left\langle\varphi\left(\mathbf{x}_{i}\right), f\right\rangle_{\mathcal{H}}^{2}}{\|f\|_{\mathcal{H}}^{2}} .
$$

- The $i$-th principal direction $f_{i}(i=1, \ldots, d)$ is defined by:

$$
f_{i}=\underset{f \perp\left\{f_{1}, \ldots, f_{i-1}\right\}}{\arg \max } \operatorname{vâr}\left(h_{f}\right) \text { s.t. }\|f\|_{\mathcal{H}}=1 .
$$

## Kernel Principal Component Analysis (PCA)

Let $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ be a set of data points in $\mathcal{X}$; let $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ be a positive definite kernel and $\mathcal{H}$ be its RKHS.

## Formalization

- The empirical variance captured by $h_{f}$ is:

$$
\operatorname{vâr}\left(h_{\mathbf{w}}\right)=\frac{1}{n} \sum_{i=1}^{n} \frac{\left(\mathbf{x}_{i}^{\top} \mathbf{w}\right)^{2}}{\|\mathbf{w}\|^{2}} \quad \Longrightarrow \quad \operatorname{vâr}\left(h_{f}\right):=\frac{1}{n} \sum_{i=1}^{n} \frac{f\left(\mathbf{x}_{i}\right)^{2}}{\|f\|_{\mathcal{H}}^{2}} .
$$

- The $i$-th principal direction $f_{i}(i=1, \ldots, d)$ is defined by:

$$
f_{i}=\underset{f \perp\left\{f_{1}, \ldots, f_{i-1}\right\}}{\arg \max } \sum_{i=1}^{n} f\left(\mathbf{x}_{i}\right)^{2} \text { s.t. }\|f\|_{\mathcal{H}}=1 .
$$

## Sanity check: kernel PCA with linear kernel $=P C A$

- Let $K(\mathbf{x}, \mathbf{y})=\mathbf{x}^{\top} \mathbf{y}$ be the linear kernel.
- The associated RKHS $\mathcal{H}$ is the set of linear functions:

$$
f_{\mathbf{w}}(\mathbf{x})=\mathbf{w}^{\top} \mathbf{x},
$$

endowed with the norm $\left\|f_{\mathbf{w}}\right\|_{\mathcal{H}}=\|\mathbf{w}\|_{\mathbb{R}^{d}}$.

- Therefore we can write:

$$
\operatorname{vâr}\left(h_{\mathbf{w}}\right)=\frac{1}{n} \sum_{i=1}^{n} \frac{\left(\mathbf{x}_{i}^{\top} \mathbf{w}\right)^{2}}{\|\mathbf{w}\|^{2}}=\frac{1}{n\left\|f_{\mathbf{w}}\right\|^{2}} \sum_{i=1}^{n} f_{\mathbf{w}}\left(\mathbf{x}_{i}\right)^{2}
$$

- Moreover, $\mathbf{w} \perp \mathbf{w}^{\prime} \Leftrightarrow f_{\mathbf{w}} \perp f_{\mathbf{w}^{\prime}}$.

## Kernel Principal Component Analysis (PCA)

## Solution

- Kernel PCA solves, for $i=1, \ldots, d$ :

$$
f_{i}=\underset{f \perp\left\{f_{1}, \ldots, f_{i-1}\right\}}{\arg \max } \sum_{i=1}^{n} f\left(\mathbf{x}_{i}\right)^{2} \text { s.t. }\|f\|_{\mathcal{H}}=1 .
$$

- We can apply the representer theorem (exercise: check that is is also valid in this case): for $i=1, \ldots, d$, we have:

$$
\forall \mathbf{x} \in \mathcal{X}, \quad f_{i}(\mathbf{x})=\sum_{j=1}^{n} \alpha_{i, j} K\left(\mathbf{x}_{j}, \mathbf{x}\right)
$$

with $\boldsymbol{\alpha}_{i}=\left(\alpha_{i, 1}, \ldots, \alpha_{i, n}\right)^{\top} \in \mathbb{R}^{n}$.

## Kernel Principal Component Analysis (PCA)

- Therefore we have:

$$
\left\|f_{i}\right\|_{\mathcal{H}}^{2}=\sum_{k, l=1}^{n} \alpha_{i, k} \alpha_{i, l} K\left(\mathbf{x}_{k}, \mathbf{x}_{l}\right)=\boldsymbol{\alpha}_{i}^{\top} \mathbf{K} \boldsymbol{\alpha}_{i}
$$

- Similarly:

$$
\sum_{k=1}^{n} f_{i}\left(\mathbf{x}_{k}\right)^{2}=\boldsymbol{\alpha}_{i}^{\top} \mathbf{K}^{2} \boldsymbol{\alpha}_{i}
$$

- and

$$
\left\langle f_{i}, f_{j}\right\rangle_{\mathcal{H}}=\boldsymbol{\alpha}_{i}^{\top} \mathbf{K} \boldsymbol{\alpha}_{j} .
$$

## Kernel Principal Component Analysis (PCA)

## Solution

Kernel PCA maximizes in $\boldsymbol{\alpha}$ the function:

$$
\boldsymbol{\alpha}_{i}=\underset{\boldsymbol{\alpha} \in \mathbb{R}^{n}}{\arg \max } \boldsymbol{\alpha}^{\top} \mathbf{K}^{2} \boldsymbol{\alpha}
$$

under the constraints:

$$
\left\{\begin{array}{l}
\boldsymbol{\alpha}_{i}^{\top} \mathbf{K} \boldsymbol{\alpha}_{j}=0 \text { for } j=1, \ldots, i-1 . \\
\boldsymbol{\alpha}_{i}^{\top} \mathbf{K} \boldsymbol{\alpha}_{i}=1
\end{array}\right.
$$

## Kernel Principal Component Analysis (PCA)

## Solution

- Compute the eigenvalue decomposition of the kernel matrix $\mathbf{K}=\mathbf{U} \boldsymbol{\Delta} \mathbf{U}^{\top}$, with eigenvalues $\Delta_{1} \geq \ldots \geq \Delta_{n} \geq 0$.
- After a change of variable $\boldsymbol{\beta}=\mathbf{K}^{1 / 2} \boldsymbol{\alpha}$ ( with $\mathbf{K}^{1 / 2}=\mathbf{U} \boldsymbol{\Delta}^{1 / 2} \mathbf{U}^{\top}$ ),

$$
\boldsymbol{\beta}_{i}=\underset{\boldsymbol{\beta} \in \mathbb{R}^{n}}{\arg \max } \boldsymbol{\beta}^{\top} \mathbf{K} \boldsymbol{\beta}
$$

under the constraints:

$$
\left\{\begin{array}{l}
\boldsymbol{\beta}_{i}^{\top} \boldsymbol{\beta}_{j}=0 \text { for } j=1, \ldots, i-1 . \\
\boldsymbol{\beta}_{i}^{\top} \boldsymbol{\beta}_{i}=1
\end{array}\right.
$$

- Thus, $\boldsymbol{\beta}_{i}=\mathbf{u}_{i}$ ( $i$-th eigenvector) is a solution!
- Finally, $\boldsymbol{\alpha}_{i}=\frac{1}{\sqrt{\boldsymbol{\Delta}_{i}}} \mathbf{u}_{i}$.

## Kernel Principal Component Analysis (PCA)

## Summary

(1) Center the Gram matrix
(2) Compute the first eigenvectors $\left(\mathbf{u}_{i}, \Delta_{i}\right)$
(3) Normalize the eigenvectors $\alpha_{i}=\mathbf{u}_{i} / \sqrt{\Delta_{i}}$
(1) The projections of the points onto the $i$-th eigenvector is given by $\mathbf{K} \boldsymbol{\alpha}_{i}$

## Kernel Principal Component Analysis (PCA)

## Remarks

- In this formulation, we must diagonalize the centered kernel Gram matrix, instead of the covariance matrix in the classical setting
- Exercise: check that $\mathbf{X}^{\top} \mathbf{X}$ and $\mathbf{X} \mathbf{X}^{\top}$ have the same spectrum (up to 0 eigenvalues) and that the eigenvectors are related by a simple relationship.
- This formulation remains valid for any p.d. kernel: this is kernel PCA
- Applications: nonlinear PCA with nonlinear kernels for vectors, PCA of non-vector objects (strings, graphs..) with specific kernels...

## Example

A set of 74 human tRNA sequences is analyzed using a kernel for sequences (the second-order marginalized kernel based on SCFG). This set of tRNAs contains three classes, called Ala-AGC (white circles), Asn-GTT (black circles) and Cys-GCA (plus symbols) (from Tsuda et al., 2003).

## The K-means algorithm

K-means is probably the most popular algorithm for clustering.

## Optimization point of view

Given data points $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathbb{R}^{p}$, it consists of performing alternate minimization steps for optimizing the following cost function

$$
\min _{\substack{\boldsymbol{\mu}_{j} \in \mathbb{R}^{p} \\ s_{i} \in\{1, \ldots, k\}, \text { for } \\ j=1, \ldots, k}} \sum_{i=1, \ldots, n}^{n}\left\|\mathbf{x}_{i}-\boldsymbol{\mu}_{s_{i}}\right\|_{2}^{2} .
$$

K-means alternates between two steps:
1 cluster assignment:
Given fixed $\boldsymbol{\mu}_{1}, \ldots, \boldsymbol{\mu}_{k}$, assign each $\mathbf{x}_{i}$ to its closest centroid

$$
\forall i, \quad s_{i} \in \underset{s \in\{1, \ldots, k\}}{\operatorname{argmin}}\left\|\mathbf{x}_{i}-\boldsymbol{\mu}_{s}\right\|_{2}^{2}
$$

## The K-means algorithm

K-means is probably the most popular algorithm for clustering.

## Optimization point of view

Given data points $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathbb{R}^{p}$, it consists of performing alternate minimization steps for optimizing the following cost function

$$
\min _{\substack{\boldsymbol{\mu}_{j} \in \mathbb{R}^{p} \\ s_{i} \in\{1, \ldots, k\}, \text { for } \\ j=1, \ldots, k}} \sum_{i=1, \ldots, n}^{n}\left\|\mathbf{x}_{i}-\boldsymbol{\mu}_{s_{i}}\right\|_{2}^{2} .
$$

K-means alternates between two steps:
2 centroids update:
Given the previous assignments $s_{1}, \ldots, s_{n}$, update the centroids

$$
\forall j, \quad \boldsymbol{\mu}_{j}=\underset{\boldsymbol{\mu} \in \mathbb{R}^{p}}{\operatorname{argmin}} \sum_{i: s_{i}=j}\left\|\mathbf{x}_{i}-\boldsymbol{\mu}\right\|_{2}^{2} .
$$

## The K-means algorithm

$$

K-means alternates between two steps:
2 centroids update:
Given the previous assignments $s_{1}, \ldots, s_{n}$, update the centroids

$$
\Leftrightarrow \forall j, \quad \boldsymbol{\mu}_{j}=\frac{1}{\left|C_{j}\right|} \sum_{i \in C_{j}} \mathbf{x}_{i} \quad \text { with } \quad C_{j}=\left\{i: s_{i}=j\right\}
$$

## The kernel K-means algorithm

We may now modify the objective to operate in a RKHS. Given data points $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathcal{X}$ and a p.d. kernel $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ with $\mathcal{H}$ its RKHS, the new objective becomes

## The kernel K-means algorithm

We may now modify the objective to operate in a RKHS. Given data points $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathcal{X}$ and a p.d. kernel $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ with $\mathcal{H}$ its RKHS, the new objective becomes

$$
\min _{\substack{\boldsymbol{\mu}_{j} \in \mathcal{H} \\ s_{i} \in\{1, \ldots, k\} \\ \text { for } \\ j=1, \ldots, k}} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\boldsymbol{\mu}_{s_{i}}\right\|_{\mathcal{H}}^{2} .
$$

To optimize the cost function, we will first use the following Proposition

## Proposition

The center of mass $\varphi_{n}=\frac{1}{n} \sum_{i=1}^{n} \varphi\left(\mathbf{x}_{i}\right)$ solves the following optimization problem

$$
\min _{\boldsymbol{\mu} \in \mathcal{H}} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\boldsymbol{\mu}\right\|_{\mathcal{H}}^{2} .
$$

## The kernel K-means algorithm

## Proof

$$
\begin{aligned}
\frac{1}{n} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\boldsymbol{\mu}\right\|_{\mathcal{H}}^{2} & =\frac{1}{n} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)\right\|_{\mathcal{H}}^{2}-\left\langle\frac{2}{n} \sum_{i=1}^{n} \varphi\left(\mathbf{x}_{i}\right), \boldsymbol{\mu}\right\rangle_{\mathcal{H}}+\|\boldsymbol{\mu}\|_{\mathcal{H}}^{2} \\
& =\frac{1}{n} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)\right\|_{\mathcal{H}}^{2}-2\left\langle\varphi_{n}, \boldsymbol{\mu}\right\rangle_{\mathcal{H}}+\|\boldsymbol{\mu}\|_{\mathcal{H}}^{2} \\
& =\frac{1}{n} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)\right\|_{\mathcal{H}}^{2}-\left\|\varphi_{n}\right\|_{\mathcal{H}}^{2}+\left\|\varphi_{n}-\boldsymbol{\mu}\right\|_{\mathcal{H}}^{2},
\end{aligned}
$$

which is minimum for $\boldsymbol{\mu}=\varphi_{n}$.

## The kernel K-means algorithm

Given now the objective,

$$
\min _{\substack{\boldsymbol{\mu}_{j} \in \mathcal{H} \\ s_{i} \in\{1, \ldots, k\} \\ \text { for for } i=1, \ldots, k}} \sum_{i=1, \ldots, n}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\boldsymbol{\mu}_{s_{i}}\right\|_{\mathcal{H}}^{2},
$$

we know that given assignments $s_{i}$, the optimal $\boldsymbol{\mu}_{j}$ are the centers of mass of the respective clusters and we obtain

## Greedy approach: kernel K-means

We alternate between two steps:
1 centroids update:
Given the previous assignments $s_{1}, \ldots, s_{n}$, update the centroids

$$
\forall j, \quad \boldsymbol{\mu}_{j}=\underset{\boldsymbol{\mu} \in \mathcal{H}}{\operatorname{argmin}} \sum_{i: s_{i}=j}\left\|\varphi\left(\mathbf{x}_{i}\right)-\boldsymbol{\mu}\right\|_{\mathcal{H}}^{2} .
$$

## The kernel K-means algorithm

Given now the objective,

$$
\min _{\substack{\boldsymbol{\mu}_{j} \in \mathcal{H} \\ s_{i} \in\{1, \ldots, k\} \\ \text { for for } i=1, \ldots, k}} \sum_{i=1, \ldots, n}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\boldsymbol{\mu}_{s_{i}}\right\|_{\mathcal{H}}^{2},
$$

we know that given assignments $s_{i}$, the optimal $\boldsymbol{\mu}_{j}$ are the centers of mass of the respective clusters and we obtain

Greedy approach: kernel K-means

$$
s_{i} \in \underset{s \in\{1, \ldots, k\}}{\operatorname{argmin}}\left(K\left(\mathbf{x}_{i}, \mathbf{x}_{i}\right)-\frac{2}{\left|C_{s}\right|} \sum_{j \in C_{s}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)+\frac{1}{\left|C_{s}\right|^{2}} \sum_{j, l \in C_{s}} K\left(\mathbf{x}_{j}, \mathbf{x}_{l}\right)\right) .
$$

## The kernel K-means algorithm, equivalent objective

Note that all operations are performed by manipulating kernel values $K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)$ only. Implicitly, we are optimizing in fact

$$
\min _{\substack{s_{i} \in\{1, \ldots, k\} \\ \text { for } i=1, \ldots, n}} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\frac{1}{\left|C_{s_{i}}\right|} \sum_{j \in C_{s_{i}}} \varphi\left(\mathbf{x}_{j}\right)\right\|_{\mathcal{H}}^{2},
$$

or, equivalently,
$\min _{\substack{s_{i} \in\{1, \ldots, k\} \\ \text { for } i=1, \ldots, n}} \sum_{i=1}^{n}\left(K\left(\mathbf{x}_{i}, \mathbf{x}_{i}\right)-\frac{2}{\left|C_{s_{i}}\right|} \sum_{j \in C_{s_{i}}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)+\frac{1}{\left|C_{s_{i}}\right|^{2}} \sum_{j, l \in C_{s_{i}}} K\left(\mathbf{x}_{j}, \mathbf{x}_{l}\right)\right)$.
Then, notice that

$$
\sum_{i=1}^{n} \frac{1}{\left|C_{S_{i}}\right|^{2}} \sum_{j, l \in C_{s_{i}}} K\left(\mathbf{x}_{j}, \mathbf{x}_{l}\right)=\sum_{l=1}^{k} \frac{1}{\left|C_{l}\right|} \sum_{i, j \in C_{l}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)
$$

## The kernel K-means algorithm, equivalent objective

Note that all operations are performed by manipulating kernel values $K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)$ only. Implicitly, we are optimizing in fact

$$
\min _{\substack{s_{i} \in\{1, \ldots, k\} \\ \text { for } i=1, \ldots, n}} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\frac{1}{\left|C_{s_{i}}\right|} \sum_{j \in C_{s_{i}}} \varphi\left(\mathbf{x}_{j}\right)\right\|_{\mathcal{H}}^{2}
$$

or, equivalently,
$\min _{\substack{s_{i} \in\{1, \ldots, k\} \\ \text { for } \\ i=1, \ldots, n}} \sum_{i=1}^{n}\left(K\left(\mathbf{x}_{i}, \mathbf{x}_{i}\right)-\frac{2}{\left|C_{s_{i}}\right|} \sum_{j \in C_{s_{i}}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)+\frac{1}{\left|C_{s_{i}}\right|^{2}} \sum_{j, l \in C_{s_{i}}} K\left(\mathbf{x}_{j}, \mathbf{x}_{l}\right)\right)$.
and

$$
\sum_{i=1}^{n} \frac{1}{\left|C_{S_{i}}\right|} \sum_{j \in C_{S_{i}}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)=\sum_{l=1}^{k} \frac{1}{\left|C_{l}\right|} \sum_{i, j \in C_{l}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) .
$$

## The kernel K-means algorithm, equivalent objective

Then, after removing the constant terms $K\left(\mathbf{x}_{i}, \mathbf{x}_{i}\right)$, we obtain:

## Proposition

The kernel K-means objective is equivalent to the following one:

$$
\max _{\substack{s_{i} \in\{1, \ldots, k\} \\ \text { for } i=1, \ldots, n}} \sum_{l=1}^{k} \frac{1}{\left|C_{l}\right|} \sum_{i, j \in C_{l}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) .
$$

This is a hard combinatorial optimization problem.
There are two types of algorithms to address it:

## The kernel K-means algorithm, equivalent objective

Then, after removing the constant terms $K\left(\mathbf{x}_{i}, \mathbf{x}_{i}\right)$, we obtain:

## Proposition

The kernel K-means objective is equivalent to the following one:

$$
\max _{\substack{s_{i} \in\{1, \ldots, k\} \\ \text { for } \\ i=1, \ldots, n}} \sum_{l=1}^{k} \frac{1}{\left|C_{l}\right|} \sum_{i, j \in C_{l}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) .
$$

This is a hard combinatorial optimization problem.
There are two types of algorithms to address it:
(1) greedy algorithm: kernel K-means
(2) spectral relaxation: spectral clustering

## Spectral clustering algorithms

Instead of a greedy approach, we can relax the problem into a feasible one, which yields a class of algorithms called spectral clustering.

First, consider the objective

$$
\max _{\substack{s_{i} \in\{1, \ldots, k\} \\ \text { for } i=1, \ldots, n}} \sum_{l=1}^{k} \frac{1}{\left|C_{l}\right|} \sum_{i, j \in C_{l}} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)
$$

and we introduce
$(\star)$ the binary assignment matrix $\mathbf{A}$ in $\{0,1\}^{n \times k}$ whose rows sum to one.
$(* *)$ the diagonal rescaling matrix $\mathbf{D}$ in $\mathbb{R}^{k \times k}$ with diagonal entries $[\mathbf{D}]_{j j}$ equal to $\left(\sum_{i=1}^{n}[\mathbf{A}]_{i j}\right)^{-1}$ : the inverse of the cardinality of cluster $j$. and the objective can be rewritten (proof is easy and left as an exercise)

$$
\max _{\mathbf{A}, \mathbf{D}}\left[\operatorname{trace}\left(\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{K} \mathbf{A} \mathbf{D}^{1 / 2}\right)\right] \text { s.t. }(\star) \text { and }(\star \star) .
$$

## Spectral clustering algorithms

$$
\max _{\mathbf{A}, \mathbf{D}} \operatorname{trace}\left(\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{K} \mathbf{A} \mathbf{D}^{1 / 2}\right) \text { s.t. }(\star) \text { and }(\star \star) \text {. }
$$

The constraints on $\mathbf{A}, \mathbf{D}$ are such that $\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{A} \mathbf{D}^{1 / 2}=\mathbf{I}$ (exercise). $\mathbf{A}$ natural relaxation consists of dropping the constraints $(\star, \star \star)$ on $\mathbf{A}$ and $\mathbf{D}$ and instead optimize over $\mathbf{Z}=\mathbf{A D} \mathbf{D}^{1 / 2}$ :

$$
\max _{\mathbf{Z} \in \mathbb{R}^{n \times k}} \operatorname{trace}\left(\mathbf{Z}^{\top} \mathbf{K} \mathbf{Z}\right) \text { s.t. } \mathbf{Z}^{\top} \mathbf{Z}=\mathbf{I} .
$$

## Spectral clustering algorithms

$$
\max _{\mathbf{A}, \mathbf{D}} \operatorname{trace}\left(\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{K} \mathbf{A} \mathbf{D}^{1 / 2}\right) \text { s.t. }(\star) \text { and }(\star \star) \text {. }
$$

The constraints on $\mathbf{A}, \mathbf{D}$ are such that $\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{A} \mathbf{D}^{1 / 2}=\mathbf{I}$ (exercise). A natural relaxation consists of dropping the constraints $(\star, \star \star)$ on $\mathbf{A}$ and $\mathbf{D}$ and instead optimize over $\mathbf{Z}=\mathbf{A} \mathbf{D}^{1 / 2}$ :

$$
\max _{\mathbf{Z} \in \mathbb{R}^{n \times k}} \operatorname{trace}\left(\mathbf{Z}^{\top} \mathbf{K} \mathbf{Z}\right) \text { s.t. } \mathbf{Z}^{\top} \mathbf{Z}=\mathbf{I} .
$$

A solution $\mathbf{Z}^{\star}$ to this problem may be obtained by computing the eigenvectors of $\mathbf{K}$ associated to the $k$-largest eigenvalues. This procedure is related to the kernel PCA algorithm!

## Question

How do we obtain an approximate solution (A, D) of the original problem from the exact solution of the relaxed one $\mathbf{Z}^{\star}$ ?

## Spectral clustering algorithms

$$
\max _{\mathbf{A}, \mathbf{D}} \operatorname{trace}\left(\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{K} \mathbf{A} \mathbf{D}^{1 / 2}\right) \text { s.t. }(\star) \text { and }(\star \star) \text {. }
$$

The constraints on $\mathbf{A}, \mathbf{D}$ are such that $\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{A} \mathbf{D}^{1 / 2}=\mathbf{I}$ (exercise). $\mathbf{A}$ natural relaxation consists of dropping the constraints $(\star, \star \star)$ on $\mathbf{A}$ and $\mathbf{D}$ and instead optimize over $\mathbf{Z}=\mathbf{A} \mathbf{D}^{1 / 2}$ :

$$
\max _{\mathbf{Z} \in \mathbb{R}^{n \times k}} \operatorname{trace}\left(\mathbf{Z}^{\top} \mathbf{K} \mathbf{Z}\right) \text { s.t. } \mathbf{Z}^{\top} \mathbf{Z}=\mathbf{I} .
$$

A solution $\mathbf{Z}^{\star}$ to this problem may be obtained by computing the eigenvectors of $\mathbf{K}$ associated to the $k$-largest eigenvalues. This procedure is related to the kernel PCA algorithm!

Answer 1
With the original constraints on $\mathbf{A}$, every row of $\mathbf{A}$ has a single non-zero entry $\Rightarrow$ compute the maximum entry of every row of $\mathbf{Z}^{\star}$.

## Spectral clustering algorithms

$$
\max _{\mathbf{A}, \mathbf{D}} \operatorname{trace}\left(\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{K} \mathbf{A} \mathbf{D}^{1 / 2}\right) \text { s.t. }(\star) \text { and }(\star \star) \text {. }
$$

The constraints on $\mathbf{A}, \mathbf{D}$ are such that $\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{A} \mathbf{D}^{1 / 2}=\mathbf{I}$ (exercise). $\mathbf{A}$ natural relaxation consists of dropping the constraints $(\star, \star \star)$ on $\mathbf{A}$ and $\mathbf{D}$ and instead optimize over $\mathbf{Z}=\mathbf{A} \mathbf{D}^{1 / 2}$ :

$$
\max _{\mathbf{Z} \in \mathbb{R}^{n \times k}} \operatorname{trace}\left(\mathbf{Z}^{\top} \mathbf{K} \mathbf{Z}\right) \text { s.t. } \mathbf{Z}^{\top} \mathbf{Z}=\mathbf{I} .
$$

A solution $\mathbf{Z}^{\star}$ to this problem may be obtained by computing the eigenvectors of $\mathbf{K}$ associated to the $k$-largest eigenvalues. This procedure is related to the kernel PCA algorithm!

Answer 2
Normalize the rows of $\mathbf{Z}^{\star}$ to have unit $\ell_{2}$-norm, and apply the traditional K -means algorithm on the rows. This is called spectral clustering.

## Spectral clustering algorithms

$$
\max _{\mathbf{A}, \mathbf{D}} \operatorname{trace}\left(\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{K} \mathbf{A} \mathbf{D}^{1 / 2}\right) \text { s.t. }(\star) \text { and }(\star \star) \text {. }
$$

The constraints on $\mathbf{A}, \mathbf{D}$ are such that $\mathbf{D}^{1 / 2} \mathbf{A}^{\top} \mathbf{A} \mathbf{D}^{1 / 2}=\mathbf{I}$ (exercise). A natural relaxation consists of dropping the constraints $(\star, \star \star)$ on $\mathbf{A}$ and $\mathbf{D}$ and instead optimize over $\mathbf{Z}=\mathbf{A} \mathbf{D}^{1 / 2}$ :

$$
\max _{\mathbf{Z} \in \mathbb{R}^{n \times k}} \operatorname{trace}\left(\mathbf{Z}^{\top} \mathbf{K} \mathbf{Z}\right) \text { s.t. } \mathbf{Z}^{\top} \mathbf{Z}=\mathbf{I} .
$$

A solution $\mathbf{Z}^{\star}$ to this problem may be obtained by computing the eigenvectors of $\mathbf{K}$ associated to the $k$-largest eigenvalues. This procedure is related to the kernel PCA algorithm!

Answer 3
Choose another variant of the previous procedures.

6 Open Problems and Research Topics

## Canonical Correlation Analysis (CCA)

Given two views $\mathbf{X}=\left[\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right]$ in $\mathbb{R}^{p \times n}$ and $\mathbf{Y}=\left[\mathbf{y}_{1}, \ldots, \mathbf{y}_{n}\right]$ in $\mathbb{R}^{d \times n}$ of the same dataset, the goal of canonical correlation analysis (CCA) is to find pairs of directions in the two views that are maximally correlated.

## Formulation

Assuming that the datasets are centered, we want to maximize

$$
\max _{\mathbf{w}_{a} \in \mathbb{R}^{\rho}, \mathbf{w}_{b} \in \mathbb{R}^{d}} \frac{\frac{1}{n} \sum_{i=1}^{n} \mathbf{w}_{a}^{\top} \mathbf{x}_{i} \mathbf{y}_{i}^{\top} \mathbf{w}_{b}}{\left(\frac{1}{n} \sum_{i=1}^{n} \mathbf{w}_{a}^{\top} \mathbf{x}_{i} \mathbf{x}_{i}^{\top} \mathbf{w}_{a}\right)^{1 / 2}\left(\frac{1}{n} \sum_{i=1}^{n} \mathbf{w}_{b}^{\top} \mathbf{y}_{i} \mathbf{y}_{i}^{\top} \mathbf{w}_{b}\right)^{1 / 2}} .
$$

Assuming that the pairs $\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right)$ are i.i.d. samples from an unknown distribution, CCA seeks to maximize

$$
\max _{\mathbf{w}_{a} \in \mathbb{R}^{p}, \mathbf{w}_{b} \in \mathbb{R}^{d}} \frac{\operatorname{cov}\left(\mathbf{w}_{a}^{\top} X, \mathbf{w}_{b}^{\top} Y\right)}{\sqrt{\operatorname{var}\left(\mathbf{w}_{a}^{\top} X\right)} \sqrt{\operatorname{var}\left(\mathbf{w}_{b}^{\top} Y\right)}}
$$

## Canonical Correlation Analysis (CCA)

Given two views $\mathbf{X}=\left[\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right]$ in $\mathbb{R}^{p \times n}$ and $\mathbf{Y}=\left[\mathbf{y}_{1}, \ldots, \mathbf{y}_{n}\right]$ in $\mathbb{R}^{d \times n}$ of the same dataset, the goal of canonical correlation analysis (CCA) is to find pairs of directions in the two views that are maximally correlated.

## Formulation

Assuming that the datasets are centered, we want to maximize

$$
\max _{\mathbf{w}_{a} \in \mathbb{R}^{P}, \mathbf{w}_{b} \in \mathbb{R}^{d}} \frac{\frac{1}{n} \sum_{i=1}^{n} \mathbf{w}_{a}^{\top} \mathbf{x}_{i} \mathbf{y}_{i}^{\top} \mathbf{w}_{b}}{\left(\frac{1}{n} \sum_{i=1}^{n} \mathbf{w}_{a}^{\top} \mathbf{x}_{i} \mathbf{x}_{i}^{\top} \mathbf{w}_{a}\right)^{1 / 2}\left(\frac{1}{n} \sum_{i=1}^{n} \mathbf{w}_{b}^{\top} \mathbf{y}_{i} \mathbf{y}_{i}^{\top} \mathbf{w}_{b}\right)^{1 / 2}} .
$$

It is possible to show that this is an generalized eigenvalue problem (see next slide or see Section 6.5 of Shawe-Taylor and Cristianini 2004b).

The above problem provides the first pair of canonical directions. Next directions can be obtained by solving the same problem under the constraint that they are orthogonal to the previous canonical directions.

## Canonical Correlation Analysis (CCA)

## Formulation

Assuming that the datasets are centered,

$$
\max _{\mathbf{w}_{a} \in \mathbb{R}^{P}, \mathbf{w}_{b} \in \mathbb{R}^{d}} \frac{\mathbf{w}_{a}^{\top} \mathbf{X}^{\top} \mathbf{Y} \mathbf{w}_{b}}{\left(\mathbf{w}_{a}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}_{a}\right)^{1 / 2}\left(\mathbf{w}_{b}^{\top} \mathbf{Y}^{\top} \mathbf{Y} \mathbf{w}_{b}\right)^{1 / 2}} .
$$

can be formulated, after removing the scaling ambiguity, as

$$
\max _{\mathbf{w}_{a} \in \mathbb{R}^{\rho}, \mathbf{w}_{b} \in \mathbb{R}^{d}} \mathbf{w}_{a}^{\top} \mathbf{X}^{\top} \mathbf{Y} \mathbf{w}_{b} \text { s.t. } \mathbf{w}_{a}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}_{a}=1 \text { and } \mathbf{w}_{b}^{\top} \mathbf{Y}^{\top} \mathbf{Y} \mathbf{w}_{b}=1 .
$$

Then, there exists $\lambda_{a}$ and $\lambda_{b}$ such that the problem is equivalent to

$$
\min _{\mathbf{w}_{a} \in \mathbb{R}^{\rho}, \mathbf{w}_{b} \in \mathbb{R}^{d}}-\mathbf{w}_{a}^{\top} \mathbf{X}^{\top} \mathbf{Y} \mathbf{w}_{b}+\frac{\lambda_{a}}{2}\left(\mathbf{w}_{a}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}_{a}-1\right)+\frac{\lambda_{b}}{2}\left(\mathbf{w}_{b}^{\top} \mathbf{Y}^{\top} \mathbf{Y} \mathbf{w}_{b}-1\right) .
$$

## Canonical Correlation Analysis (CCA)

Taking the derivatives and setting the gradient to zero, we obtain

$$
\begin{aligned}
& -\mathbf{X}^{\top} \mathbf{Y} \mathbf{w}_{b}+\lambda_{a} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}_{a}=0 \\
& -\mathbf{Y}^{\top} \mathbf{X} \mathbf{w}_{a}+\lambda_{b} \mathbf{Y}^{\top} \mathbf{Y} \mathbf{w}_{b}=0
\end{aligned}
$$

Multiply first equality by $\mathbf{w}_{a}^{\top}$ and second equality by $\mathbf{w}_{b}^{\top}$; subtract the two resulting equalities and we get

$$
\lambda_{a} \mathbf{w}_{a}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}_{a}=\lambda_{b} \mathbf{w}_{b}^{\top} \mathbf{Y}^{\top} \mathbf{Y} \mathbf{w}_{b}=\lambda_{a}=\lambda_{b}=\lambda,
$$

and then, we obtain the generalized eigenvalue problem:

$$
\left[\begin{array}{cc}
0 & \mathbf{X}^{\top} \mathbf{Y} \\
\mathbf{Y}^{\top} \mathbf{X} & 0
\end{array}\right]\left[\begin{array}{l}
\mathbf{w}_{a} \\
\mathbf{w}_{b}
\end{array}\right]=\lambda\left[\begin{array}{cc}
\mathbf{X}^{\top} \mathbf{X} & 0 \\
0 & \mathbf{Y}^{\top} \mathbf{Y}
\end{array}\right]\left[\begin{array}{l}
\mathbf{w}_{a} \\
\mathbf{w}_{b}
\end{array}\right]
$$

## Canonical Correlation Analysis (CCA)

Let us define

$$
\boldsymbol{\Sigma}_{A}=\left[\begin{array}{cc}
0 & \mathbf{X}^{\top} \mathbf{Y} \\
\mathbf{Y}^{\top} \mathbf{X} & 0
\end{array}\right], \quad \boldsymbol{\Sigma}_{B}=\left[\begin{array}{cc}
\mathbf{X}^{\top} \mathbf{X} & 0 \\
0 & \mathbf{Y}^{\top} \mathbf{Y}
\end{array}\right] \quad \text { and } \quad \mathbf{w}=\left[\begin{array}{c}
\mathbf{w}_{a} \\
\mathbf{w}_{b}
\end{array}\right]
$$

Assuming the covariances are invertible, the generalized eigenvalue problem is equivalent to

$$
\boldsymbol{\Sigma}_{B}^{-1 / 2} \boldsymbol{\Sigma}_{A} \mathbf{w}=\lambda \boldsymbol{\Sigma}_{B}^{1 / 2} \mathbf{w}
$$

which is also equivalent to the eigenvalue problem

$$
\boldsymbol{\Sigma}_{B}^{-1 / 2} \boldsymbol{\Sigma}_{A} \boldsymbol{\Sigma}_{B}^{-1 / 2}\left(\boldsymbol{\Sigma}_{B}^{1 / 2} \mathbf{w}\right)=\lambda\left(\boldsymbol{\Sigma}_{B}^{1 / 2} \mathbf{w}\right)
$$

## Kernel Canonical Correlation Analysis

Similar to kernel PCA, it is possible to operate in a RKHS. Given two p.d. kernels $K_{a}, K_{b}: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$, we can obtain two "views" of a dataset $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathcal{X}^{n}$ :

$$
\left(\varphi_{a}\left(\mathbf{x}_{1}\right), \ldots, \varphi_{a}\left(\mathbf{x}_{n}\right)\right) \quad \text { and } \quad\left(\varphi_{b}\left(\mathbf{x}_{1}\right), \ldots, \varphi_{b}\left(\mathbf{x}_{n}\right)\right),
$$

where $\varphi_{a}: \mathcal{X} \rightarrow \mathcal{H}_{a}$ and $\varphi_{b}: \mathcal{X} \rightarrow \mathcal{H}_{b}$ are the embeddings in the RKHSs $\mathcal{H}_{a}$ of $K_{a}$ and $\mathcal{H}_{b}$ of $K_{b}$, respectively.

## Formulation

Then, we may formulate kernel CCA as

$$
\max _{f_{a} \in \mathcal{H}_{a}, f_{b} \in \mathcal{H}_{b}} \frac{\frac{1}{n} \sum_{i=1}^{n}\left\langle f_{a}, \varphi_{a}\left(\mathbf{x}_{i}\right)\right\rangle_{\mathcal{H}_{a}}\left\langle\varphi_{b}\left(\mathbf{x}_{i}\right), f_{b}\right\rangle_{\mathcal{H}_{b}}}{\left(\frac{1}{n} \sum_{i=1}^{n}\left\langle f_{a}, \varphi_{a}\left(\mathbf{x}_{i}\right)\right\rangle_{\mathcal{H}_{a}}^{2}\right)^{1 / 2}\left(\frac{1}{n} \sum_{i=1}^{n}\left\langle f_{b}, \varphi_{b}\left(\mathbf{x}_{i}\right)\right\rangle_{\mathcal{H}_{b}}^{2}\right)^{1 / 2}} .
$$

## Kernel Canonical Correlation Analysis

Similar to kernel PCA, it is possible to operate in a RKHS. Given two p.d. kernels $K_{a}, K_{b}: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$, we can obtain two "views" of a dataset $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathcal{X}^{n}$ :

$$
\left(\varphi_{a}\left(\mathbf{x}_{1}\right), \ldots, \varphi_{a}\left(\mathbf{x}_{n}\right)\right) \quad \text { and } \quad\left(\varphi_{b}\left(\mathbf{x}_{1}\right), \ldots, \varphi_{b}\left(\mathbf{x}_{n}\right)\right),
$$

where $\varphi_{a}: \mathcal{X} \rightarrow \mathcal{H}_{a}$ and $\varphi_{b}: \mathcal{X} \rightarrow \mathcal{H}_{b}$ are the embeddings in the RKHSs $\mathcal{H}_{a}$ of $K_{a}$ and $\mathcal{H}_{b}$ of $K_{b}$, respectively.

## Formulation

Then, we may formulate kernel CCA as

$$
\max _{f_{a} \in \mathcal{H}_{a}, f_{b} \in \mathcal{H}_{b}} \frac{\frac{1}{n} \sum_{i=1}^{n} f_{a}\left(\mathbf{x}_{i}\right) f_{b}\left(\mathbf{x}_{i}\right)}{\left(\frac{1}{n} \sum_{i=1}^{n} f_{a}\left(\mathbf{x}_{i}\right)^{2}\right)^{1 / 2}\left(\frac{1}{n} \sum_{i=1}^{n} f_{b}\left(\mathbf{x}_{i}\right)^{2}\right)^{1 / 2}} .
$$

## Kernel Canonical Correlation Analysis

Up to a few technical details (exercise), we can apply the representer theorem and look for solutions $f_{a}()=.\sum_{i=1}^{n} \alpha_{i} K_{a}\left(\mathbf{x}_{i},.\right)$ and $f_{b}()=.\sum_{i=1}^{n} \beta_{i} K_{b}\left(\mathbf{x}_{i},.\right)$. We finally obtain the formulation

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{n}} \frac{\frac{1}{n} \sum_{i=1}^{n}\left[\mathbf{K}_{a} \boldsymbol{\alpha}\right]_{i}\left[\mathbf{K}_{b} \boldsymbol{\beta}\right]_{i}}{\left(\frac{1}{n} \sum_{i=1}^{n}\left[\mathbf{K}_{a} \boldsymbol{\alpha}\right]_{i}^{2}\right)^{1 / 2}\left(\frac{1}{n} \sum_{i=1}^{n}\left[\mathbf{K}_{b} \boldsymbol{\beta}\right]_{i}^{2}\right)^{1 / 2}}
$$

which is equivalent to

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{n}} \frac{\boldsymbol{\alpha}^{\top} \mathbf{K}_{a} \mathbf{K}_{b} \boldsymbol{\beta}}{\left(\boldsymbol{\alpha}^{\top} \mathbf{K}_{a}^{2} \boldsymbol{\alpha}\right)^{1 / 2}\left(\boldsymbol{\beta}^{\top} \mathbf{K}_{b}^{2} \boldsymbol{\beta}\right)^{1 / 2}}
$$

or, after removing the scaling ambiguity for $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$,

## Equivalent formulation

$$
\max _{\alpha \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{n}} \boldsymbol{\alpha}^{\top} \mathbf{K}_{a} \mathbf{K}_{b} \boldsymbol{\beta} \text { s.t. } \boldsymbol{\alpha}^{\top} \mathbf{K}_{a}^{2} \boldsymbol{\alpha}=1 \text { and } \boldsymbol{\beta}^{\top} \mathbf{K}_{b}^{2} \boldsymbol{\beta}=1 .
$$

## Kernel Canonical Correlation Analysis

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{\boldsymbol{n}}} \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{a} \mathbf{K}_{b} \boldsymbol{\beta} \text { s.t. } \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{a}^{2} \boldsymbol{\alpha}=1 \text { and } \boldsymbol{\beta}^{\top} \boldsymbol{K}_{b}^{2} \boldsymbol{\beta}=1 .
$$

- This also leads to a generalized eigenvalue problem.
- The subsequent canonical directions are obtained by solving the same problem with additional orthogonality constraints.

## Kernel Canonical Correlation Analysis

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{\boldsymbol{n}}} \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{a} \mathbf{K}_{b} \boldsymbol{\beta} \text { s.t. } \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{a}^{2} \boldsymbol{\alpha}=1 \text { and } \boldsymbol{\beta}^{\top} \boldsymbol{K}_{b}^{2} \boldsymbol{\beta}=1 .
$$

- This also leads to a generalized eigenvalue problem.
- The subsequent canonical directions are obtained by solving the same problem with additional orthogonality constraints.

What is wrong here?

## Kernel Canonical Correlation Analysis

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{\boldsymbol{n}}} \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{\mathrm{a}} \mathbf{K}_{b} \boldsymbol{\beta} \text { s.t. } \boldsymbol{\alpha}^{\top} \mathbf{K}_{a}^{2} \boldsymbol{\alpha}=1 \text { and } \boldsymbol{\beta}^{\top} \boldsymbol{K}_{b}^{2} \boldsymbol{\beta}=1 .
$$

- This also leads to a generalized eigenvalue problem.
- The subsequent canonical directions are obtained by solving the same problem with additional orthogonality constraints.

What is wrong here?
If $\mathbf{K}_{a}$ and $\mathbf{K}_{b}$ are invertible, make the change of variable $\boldsymbol{\alpha}^{\prime}=\mathbf{K}_{a} \boldsymbol{\alpha}$ and $\boldsymbol{\beta}^{\prime}=\mathbf{K}_{b} \boldsymbol{\beta}$, and we obtain the equivalent formulation

$$
\max _{\boldsymbol{\alpha}^{\prime} \in \mathbb{R}^{n}, \boldsymbol{\beta}^{\prime} \in \mathbb{R}^{n}} \boldsymbol{\alpha}^{\prime \top} \boldsymbol{\beta}^{\prime} \text { s.t. } \boldsymbol{\alpha}^{\prime \top} \boldsymbol{\alpha}^{\prime}=1 \text { and } \boldsymbol{\beta}^{\prime \top} \boldsymbol{\beta}^{\prime}=1 .
$$

The function is maximized for any $\boldsymbol{\alpha}^{\prime}=\boldsymbol{\beta}^{\prime}$ in $\mathbb{R}^{n}$.

## Kernel Canonical Correlation Analysis

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{\boldsymbol{n}}} \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{\mathrm{a}} \mathbf{K}_{b} \boldsymbol{\beta} \text { s.t. } \boldsymbol{\alpha}^{\top} \mathbf{K}_{a}^{2} \boldsymbol{\alpha}=1 \text { and } \boldsymbol{\beta}^{\top} \boldsymbol{K}_{b}^{2} \boldsymbol{\beta}=1 .
$$

- This also leads to a generalized eigenvalue problem.
- The subsequent canonical directions are obtained by solving the same problem with additional orthogonality constraints.

## What is wrong here?

If $\mathbf{K}_{a}$ and $\mathbf{K}_{b}$ are invertible, make the change of variable $\boldsymbol{\alpha}^{\prime}=\mathbf{K}_{a} \boldsymbol{\alpha}$ and $\boldsymbol{\beta}^{\prime}=\mathbf{K}_{b} \boldsymbol{\beta}$, and we obtain the equivalent formulation

$$
\max _{\boldsymbol{\alpha}^{\prime} \in \mathbb{R}^{n}, \boldsymbol{\beta}^{\prime} \in \mathbb{R}^{n}} \boldsymbol{\alpha}^{\prime \top} \boldsymbol{\beta}^{\prime} \text { s.t. } \boldsymbol{\alpha}^{\prime \top} \boldsymbol{\alpha}^{\prime}=1 \text { and } \boldsymbol{\beta}^{\prime \top} \boldsymbol{\beta}^{\prime}=1
$$

The function is maximized for any $\boldsymbol{\alpha}^{\prime}=\boldsymbol{\beta}^{\prime}$ in $\mathbb{R}^{n}$. In high (or infinite) dimension, it is easy to find spurious correlations.

## Spurious correlations

Spurious correlations are bad:

Age of Miss America
correlates with
Murders by steam, hot vapours and hot objects

Data sources: Wikipedia and Centers for Disease Control \& Prevention

Figure: http://www.tylervigen.com/.

## Spurious correlations

Spurious correlations are bad:

# Worldwide non-commercial space launches <br> correlates with <br> Sociology doctorates awarded (US) 

Data sources: Federal Aviation Administration and National Science Foundation

Figure: http://www.tylervigen.com/.

## Kernel Canonical Correlation Analysis

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{n}} \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{a} \mathbf{K}_{b} \boldsymbol{\beta} \text { s.t. } \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{a}^{2} \boldsymbol{\alpha}=1 \text { and } \boldsymbol{\beta}^{\top} \boldsymbol{K}_{b}^{2} \boldsymbol{\beta}=1 \text {. }
$$

- spurious correlation is a problem of overfitting;
- it also a problem of numerical instability, due to the need to invert the kernel matrices;

## Kernel Canonical Correlation Analysis

$$
\max _{\boldsymbol{\alpha} \in \mathbb{R}^{n}, \boldsymbol{\beta} \in \mathbb{R}^{\boldsymbol{n}}} \boldsymbol{\alpha}^{\top} \boldsymbol{K}_{\mathrm{a}} \mathbf{K}_{b} \boldsymbol{\beta} \text { s.t. } \boldsymbol{\alpha}^{\top} \mathbf{K}_{a}^{2} \boldsymbol{\alpha}=1 \text { and } \boldsymbol{\beta}^{\top} \boldsymbol{K}_{b}^{2} \boldsymbol{\beta}=1 .
$$

- spurious correlation is a problem of overfitting;
- it also a problem of numerical instability, due to the need to invert the kernel matrices;

A solution to both problems: Regularize!

- Find smooth directions $\left(f_{a}, f_{b}\right)$ by penalizing $\left\|f_{a}\right\|_{\mathcal{H}_{a}}$ and $\left\|f_{b}\right\|_{\mathcal{H}_{b}}$.
- it consists of replacing the constraints $\boldsymbol{\alpha}^{\top} \mathbf{K}_{a}^{2} \boldsymbol{\alpha}=1$ by

$$
(1-\tau) \boldsymbol{\alpha}^{\top} \mathbf{K}_{a}^{2} \boldsymbol{\alpha}+\tau \underbrace{\boldsymbol{\alpha}^{\top} \mathbf{K}_{a} \boldsymbol{\alpha}}_{\left\|f_{f_{a}}\right\|_{\mathcal{H}_{a}}^{2}}=1
$$

and do the same for $\boldsymbol{\beta}^{\top} \mathbf{K}_{b}^{2} \boldsymbol{\beta}=1$.

## Application of kernel CCA

Finding a joint latent representation of text (tags) and images.

(6) Open Problems and Research Topics

## Introduction

- The kernel function plays a critical role in the performance of kernel methods.
- It is the place where prior knowledge about the problem can be inserted, in particular by controlling the norm of functions in the RKHS.
- In this part we provide some intuition about the link between kernels and smoothness functional through several examples.
- Subsequent parts will focus on the design of kernels for particular types of data.

## Outline

(4) The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends - Green kernels
- Mercer kernels
- Convergence rates of KRR for Mercer kernels
- Shift-invariant kernels
- Generalization to semigroups
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Motivations

- The RKHS norm is related to the smoothness of functions.
- Smoothness of a function is naturally quantified by Sobolev norms (in particular $L_{2}$ norms of derivatives).
- Example: spline regression

$$
\min _{f} \sum_{i=1}^{n}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda \int\left(f^{\prime \prime}(t)\right)^{2} d t
$$

- In this section we make a general link between RKHS and Green functions defined by differential operators.

## A simple example

Let

$$
\mathcal{H}=\left\{f:[0,1] \mapsto \mathbb{R} \text {, absolutely continuous, } f^{\prime} \in L^{2}([0,1]), f(0)=0\right\}
$$

endowed with the bilinear form:

$$
\forall f, g \in \mathcal{H}, \quad\langle f, g\rangle_{\mathcal{H}}=\int_{0}^{1} f^{\prime}(u) g^{\prime}(u) d u
$$

Note that $\langle f, f\rangle_{\mathcal{H}}$ measures the smoothness of $f$ :

$$
\langle f, f\rangle_{\mathcal{H}}=\int_{0}^{1} f^{\prime}(u)^{2} d u=\left\|f^{\prime}\right\|_{L^{2}([0,1])}^{2}
$$

## The RKHs point of view

## Theorem

$\mathcal{H}$ is an RKHS with r.k. given by:

$$
\forall(x, y) \in[0,1]^{2}, \quad K(x, y)=\min (x, y)
$$

Therefore, the RKHS norm is precisely the smoothness functional defined in the simple example:

$$
\|f\|_{\mathcal{H}}=\left\|f^{\prime}\right\|_{L^{2}([0,1])}
$$

In particular, the following problem

$$
\min _{f \in \mathcal{H}} \sum_{i=1}^{n}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda \int_{0}^{1}\left(f^{\prime}(t)\right)^{2} d t
$$

can be reformulated as a simple kernel ridge regression problem with kernel $K(x, y)=\min (x, y)$ :

$$
\min _{f \in \mathcal{H}} \sum_{i=1}^{n}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda\|f\|_{\mathcal{H}}^{2}
$$

## Technical remark

## Definition

Let $I \subset \mathbb{R}$ an interval. A function $f: I \rightarrow \mathbb{R}$ is absolutely continuous (AC) on $I$ if for any $\epsilon>0$, there exists $\delta>0$ such that for any finite sequence of pairwise disjoint sub-intervals $\left(u_{k}, v_{k}\right) \subset I$ such that $\sum_{k}\left(v_{k}-u_{k}\right)<\delta$, it holds that $\sum_{k}\left|f\left(v_{k}\right)-f\left(u_{k}\right)\right|<\epsilon$.

- $\mathrm{AC} \Longrightarrow$ uniformly continuous $\Longrightarrow$ continuous
- $f$ AC on $[a, b] \Longleftrightarrow f$ has derivative $f^{\prime}$ almost everywhere, $f^{\prime}$ is Lebesgue integrable, and for all $x \in[a, b]$

$$
f(x)=f(a)+\int_{a}^{x} f^{\prime}(t) d t
$$

$\Longleftrightarrow$ there exists a Lebesgue integrable function $g$ on $[a, b]$ such that for all $x \in[a, b]$,

$$
f(x)=f(a)+\int_{a}^{x} g(t) d t
$$

in which case $g=f^{\prime}$ almost everywhere.

## Proof (1/5)

We need to show that
(1) $\mathcal{H}$ is a Hilbert space of functions
(2) $\forall x \in[0,1], K_{x} \in \mathcal{H}$,
(3) $\forall(x, f) \in[0,1] \times \mathcal{H},\left\langle f, K_{x}\right\rangle_{\mathcal{H}}=f(x)$.

## Proof $(2 / 5)$

$\mathcal{H}$ is a pre-Hilbert space of functions

- $\mathcal{H}$ is a vector space of functions, and $\langle f, g\rangle_{\mathcal{H}}$ a bilinear form that satisfies $\langle f, f\rangle_{\mathcal{H}} \geq 0$.
- $f$ absolutely continuous implies differentiable almost everywhere, and

$$
\forall x \in[0,1], \quad f(x)=f(0)+\int_{0}^{x} f^{\prime}(u) d u
$$

- For any $f \in \mathcal{H}, f(0)=0$ implies by Cauchy-Schwarz:

$$
|f(x)|=\left|\int_{0}^{x} f^{\prime}(u) d u\right| \leq \sqrt{x}\left(\int_{0}^{1} f^{\prime}(u)^{2} d u\right)^{\frac{1}{2}}=\sqrt{x}\langle f, f\rangle_{\mathcal{H}}^{1 / 2}
$$

Therefore, $\langle f, f\rangle_{\mathcal{H}}=0 \Longrightarrow f=0$, showing that $\langle., .\rangle_{\mathcal{H}}$ is an inner product. $\mathcal{H}$ is thus a pre-Hilbert space.

## Proof $(3 / 5)$

## $\mathcal{H}$ is a Hilbert space

- To show that $\mathcal{H}$ is complete, let $\left(f_{n}\right)_{n \in \mathbb{N}}$ a Cauchy sequence in $\mathcal{H}$
- $\left(f_{n}^{\prime}\right)_{n \in \mathbb{N}}$ is a Cauchy sequence in $L^{2}[0,1]$, thus converges to $g \in L^{2}[0,1]$
- By the previous inequality, $\left(f_{n}(x)\right)_{n \in \mathbb{N}}$ is a Cauchy sequence and thus converges to a real number $f(x)$, for any $x \in[0,1]$. Moreover:

$$
f(x)=\lim _{n} f_{n}(x)=\lim _{n} \int_{0}^{x} f_{n}^{\prime}(u) d u=\int_{0}^{x} g(u) d u
$$

showing that $f$ is absolutely continuous and $f^{\prime}=g$ almost everywhere; in particular, $f^{\prime} \in L^{2}[0,1]$.

- Finally, $f(0)=\lim _{n} f_{n}(0)=0$, therefore $f \in \mathcal{H}$ and

$$
\lim _{n}\left\|f_{n}-f\right\|_{\mathcal{H}}=\left\|f^{\prime}-g_{n}\right\|_{L^{2}([0,1])}=0
$$

## Proof $(4 / 5)$

## $\forall x \in[0,1], K_{x} \in \mathcal{H}$

- Let $K_{x}(y)=K(x, y)=\min (x, y)$ sur $[0,1]^{2}$ :

- $K_{x}$ is differentiable except at $s$, has a square integrable derivative, and $K_{x}(0)=0$, therefore $K_{x} \in \mathcal{H}$ for all $x \in[0,1]$.

## Proof $(5 / 5)$

For all $x, f,\left\langle f, K_{x}\right\rangle_{\mathcal{H}}=f(x)$

- For any $x \in[0,1]$ and $f \in \mathcal{H}$ we have:

$$
\left\langle f, K_{x}\right\rangle_{\mathcal{H}}=\int_{0}^{1} f^{\prime}(u) K_{x}^{\prime}(u) d u=\int_{0}^{x} f^{\prime}(u) d u=f(x)
$$

- This shows that $\mathcal{H}$ is a RKHS with $K$ as r.k. $\square$

## Generalization

## Theorem

Let $\mathcal{X}=\mathbb{R}^{d}$ and $D$ a differential operator on a class of functions $\mathcal{H}$ such that, endowed with the inner product:

$$
\forall(f, g) \in \mathcal{H}^{2}, \quad\langle f, g\rangle_{\mathcal{H}}=\langle D f, D g\rangle_{L^{2}(\mathcal{X})}
$$

it is a Hilbert space.
Then $\mathcal{H}$ is a RKHS that admits as r.k. the Green function of the operator $D^{*} D$, where $D^{*}$ denotes the adjoint operator of $D$.

## Green function?

## Definition

Let the differential equation on $\mathcal{H}$ :

$$
f=D g
$$

where $g$ is unknown. In order to solve it we can look for $g$ of the form:

$$
g(x)=\int_{\mathcal{X}} k(x, y) f(y) d y
$$

for some function $k: \mathcal{X}^{2} \mapsto \mathbb{R}$. $k$ must then satisfy, for all $x \in \mathcal{X}$,

$$
f(x)=D g(x)=\left\langle D k_{x}, f\right\rangle_{L^{2}(\mathcal{X})}
$$

If such a $k$ exists, it is called the Green function of the operator $D$.

## Proof

- Let $\mathcal{H}$ be a Hilbert space endowed with the inner product:

$$
\langle f, g\rangle_{\mathcal{X}}=\langle D f, D g\rangle_{L^{2}(\mathcal{X})}
$$

and $K$ be the Green function of the operator $D^{*} D$.

- For all $x \in \mathcal{X}, K_{x} \in \mathcal{H}$ because:

$$
\left\langle D K_{x}, D K_{x}\right\rangle_{L^{2}(\mathcal{X})}=\left\langle D^{*} D K_{x}, K_{x}\right\rangle_{L^{2}(\mathcal{X})}=K_{x}(x)<\infty .
$$

(caveat: sometimes other conditions must be fulfilled to be in $\mathcal{H}$, to be checked on a case by case basis).

- Moreover, for all $f \in \mathcal{H}$ and $x \in \mathcal{X}$, we have:

$$
f(x)=\left\langle D^{*} D K_{x}, f\right\rangle_{L^{2}(\mathcal{X})}=\left\langle D K_{x}, D f\right\rangle_{L^{2}(\mathcal{X})}=\left\langle K_{x}, f\right\rangle_{\mathcal{H}} .
$$

- This shows that $\mathcal{H}$ is a RKHS with $K$ as r.k. $\square$

## Example

- Back to our example, take $\mathcal{X}=[0,1]$ and $\operatorname{Df}(u)=f^{\prime}(u)$
- To find the r.k. of $\mathcal{H}$ we need to solve in $k$ :

$$
\begin{aligned}
f(x) & =\left\langle D^{*} D k_{x}, f\right\rangle_{L^{2}([0,1])} \\
& =\left\langle D k_{x}, D f\right\rangle_{L^{2}([0,1])} \\
& =\int_{0}^{1} k_{x}^{\prime}(u) f^{\prime}(u) d u
\end{aligned}
$$

- The solution is

$$
k_{x}^{\prime}(u)=\mathbf{1}_{[0, x]}(u)
$$

which gives

$$
k_{x}(u)= \begin{cases}u & \text { if } u \leq x \\ x & \text { otherwise }\end{cases}
$$

and therefore

$$
k\left(x, x^{\prime}\right)=\min \left(x, x^{\prime}\right)
$$

## Outline

## Mercer kernels

## Definition

A kernel $K$ on a set $\mathcal{X}$ is called a Mercer kernel if:
(1) $\mathcal{X}$ is a compact metric space (typically, a closed bounded subset of $\mathbb{R}^{d}$ ).
(2) $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ is a continuous p.d. kernel (w.r.t. the Borel topology)

Motivations

- We can exhibit an explicit and intuitive feature space for a large class of p.d. kernels
- Historically, provided the first proof that a p.d. kernel is an inner product for non-finite sets $\mathcal{X}$ (Mercer, 1905).
- Can be thought of as the natural generalization of the factorization of positive semidefinite matrices over infinite spaces.

## Sketch of the proof that a Mercer kernel is an inner product

(1) The kernel matrix when $\mathcal{X}$ is finite becomes a linear operator when $\mathcal{X}$ is a metric space.
(2) The matrix was positive semidefinite in the finite case, the linear operator is self-adjoint and positive in the metric case.
(3) The spectral theorem states that any compact linear operator admits a complete orthonormal basis of eigenfunctions, with non-negative eigenvalues (just like positive semidefinite matrices can be diagonalized with nonnegative eigenvalues).
(9) The kernel function can then be expanded over basis of eigenfunctions as:

$$
K(\mathbf{x}, \mathbf{t})=\sum_{k=1}^{\infty} \lambda_{k} \psi_{k}(\mathbf{x}) \psi_{k}(\mathbf{t})
$$

where $\lambda_{i} \geq 0$ are the non-negative eigenvalues.

## In case of...

## Definition

Let $\mathcal{H}$ be a Hilbert space

- A linear operator is a continuous linear mapping from $\mathcal{H}$ to itself.
- A linear operator $L$ is called compact if, for any bounded sequence $\left\{f_{n}\right\}_{n=1}^{\infty}$, the sequence $\left\{L f_{n}\right\}_{n=1}^{\infty}$ has a subsequence that converges.
- $L$ is called self-adjoint if, for any $f, g \in \mathcal{H}$ :

$$
\langle f, L g\rangle=\langle L f, g\rangle .
$$

- $L$ is called positive if it is self-adjoint and, for any $f \in \mathcal{H}$ :

$$
\langle f, L f\rangle \geq 0
$$

## An important lemma

## The linear operator

- Let $\nu$ be any Borel measure on $\mathcal{X}$, and $L_{\nu}^{2}(\mathcal{X})$ the Hilbert space of (equivalence classes of) square integrable functions on $\mathcal{X}$.
- For any function $K: \mathcal{X}^{2} \mapsto \mathbb{R}$, let the transform:

$$
\forall f \in L_{\nu}^{2}(\mathcal{X}), \quad\left(L_{K} f\right)(\mathbf{x})=\int K(\mathbf{x}, \mathbf{t}) f(\mathbf{t}) d \nu(\mathbf{t})
$$

## Lemma

If $K$ is a Mercer kernel, then $L_{K}$ is a compact and bounded linear operator over $L_{\nu}^{2}(\mathcal{X})$, self-adjoint and positive.

## Proof (1/6)

## $L_{K}$ is a mapping from $L_{\nu}^{2}(\mathcal{X})$ to $L_{\nu}^{2}(\mathcal{X})$

For any $f \in L_{\nu}^{2}(\mathcal{X})$ and $\left(\mathbf{x}_{1}, \mathbf{x}_{1}\right) \in \mathcal{X}^{2}$ :

$$
\begin{aligned}
&\left|\left(L_{K} f\right)\left(\mathbf{x}_{1}\right)-\left(L_{K} f\right)\left(\mathbf{x}_{2}\right)\right|=\left|\int\left(K\left(\mathbf{x}_{1}, \mathbf{t}\right)-K\left(\mathbf{x}_{2}, \mathbf{t}\right)\right) f(\mathbf{t}) d \nu(\mathbf{t})\right| \\
&=\left\langle K_{\mathbf{x}_{1}}-K_{\mathbf{x}_{2}}, f\right\rangle_{L_{\nu}^{2}(\mathcal{X})} \\
& \leq\left\|K_{\mathbf{x}_{1}}-K_{\mathbf{x}_{2}}\right\|_{L_{\nu}^{2}(\mathcal{X})}\|f\|_{L_{\nu}^{2}(\mathcal{X})} \\
& \quad \text { (Cauchy-Schwarz) }
\end{aligned}
$$

$\leq \sqrt{\nu(\mathcal{X})} \max _{\mathbf{t} \in \mathcal{X}}\left|K\left(\mathbf{x}_{1}, \mathbf{t}\right)-K\left(\mathbf{x}_{2}, \mathbf{t}\right)\right|\|f\|_{L_{\nu}^{2}(\mathcal{X})}$.
$K$ being continuous and $\mathcal{X}$ compact, $K$ is uniformly continuous, therefore $L_{K} f$ is continuous. In particular, $L_{K} f \in L_{\nu}^{2}(\mathcal{X})$ (with the slight abuse of notation $\left.\mathcal{C}(\mathcal{X}) \subset L_{\nu}^{2}(\mathcal{X})\right)$.

## Proof (2/6)

## $L_{K}$ is linear and continuous

- Linearity is obvious (by definition of $L_{K}$ and linearity of the integral).
- For continuity, we observe that for all $f \in L_{\nu}^{2}(\mathcal{X})$ and $\mathbf{x} \in \mathcal{X}$ :

$$
\begin{aligned}
\left|\left(L_{K} f\right)(\mathbf{x})\right| & =\left|\int K(\mathbf{x}, \mathbf{t}) f(\mathbf{t}) d \nu(\mathbf{t})\right| \\
& \leq \sqrt{\nu(\mathcal{X})} \max _{\mathbf{t} \in \mathcal{X}}|K(\mathbf{x}, \mathbf{t})|\|f\|_{L_{\nu}^{2}(\mathcal{X})} \\
& \leq \sqrt{\nu(\mathcal{X})} C_{K}\|f\|_{L_{\nu}^{2}(\mathcal{X})} .
\end{aligned}
$$

with $C_{K}=\max _{\mathbf{x}, \mathbf{t} \in \mathcal{X}}|K(\mathbf{x}, \mathbf{t})|<+\infty$. Therefore:

$$
\left\|L_{K} f\right\|_{L_{\nu}^{2}(\mathcal{X})}=\left(\int\left(L_{K} f\right)(\mathbf{t})^{2} d \nu(\mathbf{t})\right)^{\frac{1}{2}} \leq \nu(\mathcal{X}) C_{K}\|f\|_{L_{\nu}^{2}(\mathcal{X})}
$$

## Proof (3/6)

## Criterion for compactness

In order to prove the compactness of $L_{K}$ we need the following criterion. Let $C(\mathcal{X})$ denote the set of continuous functions on $\mathcal{X}$ endowed with infinite norm $\|f\|_{\infty}=\max _{\mathbf{x} \in \mathcal{X}}|f(\mathbf{x})|$.
A set of functions $G \subset C(\mathcal{X})$ is called equicontinuous if:

$$
\begin{aligned}
& \forall \epsilon>0, \exists \delta>0, \forall(\mathbf{x}, \mathbf{y}) \in \mathcal{X}^{2}, \\
& \qquad\|\mathbf{x}-\mathbf{y}\|<\delta \Longrightarrow \forall g \in G,|g(\mathbf{x})-g(\mathbf{y})|<\epsilon
\end{aligned}
$$

## Ascoli Theorem

A part $H \subset C(\mathcal{X})$ is relatively compact (i.e., its closure is compact) if and only if it is uniformly bounded and equicontinuous.

## Proof (4/6)

## $L_{K}$ is compact

Let $\left(f_{n}\right)_{n \geq 0}$ be a bounded sequence of $L_{\nu}^{2}(\mathcal{X})\left(\left\|f_{n}\right\|_{L_{\nu}^{2}(\mathcal{X})}<M\right.$ for all $\left.n\right)$. The sequence $\left(L_{K} f_{n}\right)_{n \geq 0}$ is a sequence of continuous functions, uniformly bounded because:

$$
\left\|L_{K} f_{n}\right\|_{\infty} \leq \sqrt{\nu(\mathcal{X})} C_{K}\left\|f_{n}\right\|_{L_{\nu}^{2}(\mathcal{X})} \leq \sqrt{\nu(\mathcal{X})} C_{K} M
$$

It is equicontinuous because:

$$
\left|L_{K} f_{n}\left(\mathbf{x}_{1}\right)-L_{K} f_{n}\left(\mathbf{x}_{2}\right)\right| \leq \sqrt{\nu(\mathcal{X})} \max _{\mathbf{t} \in \mathcal{X}}\left|K\left(\mathbf{x}_{1}, \mathbf{t}\right)-K\left(\mathbf{x}_{2}, \mathbf{t}\right)\right| M
$$

By Ascoli theorem, we can extract a sequence uniformly convergent in $C(\mathcal{X})$, and therefore in $L_{\nu}^{2}(\mathcal{X})$.

## Proof (5/6)

## $L_{K}$ is self-adjoint

$K$ being symmetric, we have for all $f, g \in L_{\nu}^{2}(\mathcal{X})$ :

$$
\begin{aligned}
\langle f, L g\rangle_{L_{\nu}^{2}(\mathcal{X})} & =\int f(\mathbf{x})(L g)(\mathbf{x}) d \nu(\mathbf{x}) \\
& =\iint f(\mathbf{x}) g(\mathbf{t}) K(\mathbf{x}, \mathbf{t}) d \nu(\mathbf{x}) d \nu(\mathbf{t}) \\
& =\langle L f, g\rangle_{L_{\nu}^{2}(\mathcal{X})}
\end{aligned}
$$

## Proof $(6 / 6)$

## $L_{K}$ is positive

We can approximate the integral by finite sums:

$$
\begin{aligned}
\langle f, L f\rangle_{L_{\nu}^{2}(\mathcal{X})} & =\iint f(\mathbf{x}) f(\mathbf{t}) K(\mathbf{x}, \mathbf{t}) \nu(d \mathbf{x}) \nu(d \mathbf{t}) \\
& =\lim _{k \rightarrow \infty} \frac{\nu(\mathcal{X})}{k^{2}} \sum_{i, j=1}^{k} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) f\left(\mathbf{x}_{i}\right) f\left(\mathbf{x}_{j}\right) \\
& \geq 0
\end{aligned}
$$

because $K$ is positive definite. $\quad \square$

## Diagonalization of the operator

We need the following general result (e.g., Debnath and Mikusiński, 2005, Section 4.10)

## Spectral theorem

Let $L$ be a compact self-adjoint linear operator on a Hilbert space $\mathcal{H}$. Then there exists in $\mathcal{H}$ a complete orthonormal system $\left(\psi_{1}, \psi_{2}, \ldots\right)$ of eigenvectors of $L$, with real eigenvalues $\left(\lambda_{1}, \lambda_{2}, \ldots\right)$ which are non-negative if $L$ is positive.

## Remark

This theorem can be applied to $L_{K}$. In that case the eigenfunctions $\psi_{k}$ associated to the eigenfunctions $\lambda_{k} \neq 0$ can be considered as continuous functions, because:

$$
\psi_{k}=\frac{1}{\lambda_{k}} L_{K} \psi_{k}
$$

## Main result

## Mercer's Theorem

Let $\mathcal{X}$ be a compact metric space, $\nu$ a nondegenerate ${ }^{\text {a }}$ Borel measure on $\mathcal{X}$, and $K$ a continuous p.d. kernel. Let $\lambda_{1} \geq \lambda_{2} \geq \ldots \geq 0$ denote the nonnegative eigenvalues of $L_{K}$ and $\left(\psi_{1}, \psi_{2}, \ldots\right)$ the corresponding eigenfunctions. Then all functions $\psi_{k}$ are continuous, and for any $\mathbf{x}, \mathbf{t} \in \mathcal{X}$ :

$$
K(\mathbf{x}, \mathbf{t})=\sum_{k=1}^{\infty} \lambda_{k} \psi_{k}(\mathbf{x}) \psi_{k}(\mathbf{t})
$$

where the convergence is absolute for each $\mathbf{x}, \mathbf{t} \in \mathcal{X}$, and uniform on $\mathcal{X} \times \mathcal{X}$.

```
ai.e., }\nu(U)>0\mathrm{ for any nonempty open set U}\subset\mathcal{X
```

## Proof of Mercer's Theorem (1/6)

## For any $k \geq 1$ such that $\lambda_{k}>0, \psi_{k} \in \mathcal{H}($ RKHS of $K)$

If $\lambda_{k}>0$, we have

$$
\begin{aligned}
\forall \mathbf{x} \in \mathcal{X}, \quad \psi_{k}(\mathbf{x}) & =\frac{1}{\lambda_{k}} L_{K} \psi_{k}(\mathbf{x}) \\
& =\frac{1}{\lambda_{k}} \int K(\mathbf{x}, \mathbf{t}) \psi_{k}(\mathbf{t}) d \nu(\mathbf{t}) \\
& =\lim _{n \rightarrow+\infty} \underbrace{\frac{\nu(\mathcal{X})}{\lambda_{k} n} \sum_{i=1}^{n} K\left(\mathbf{x}, \mathbf{t}_{i}\right) \psi_{k}\left(\mathbf{t}_{i}\right)}_{h_{n}(\mathbf{x})}
\end{aligned}
$$

for a set $\mathbf{t}_{1}, \mathbf{t}_{2}, \ldots$ conveniently chosen. Besides, $h_{n} \in \mathcal{H}$ for any $n \in \mathbb{N}$ and, for any $n, m \in \mathbb{N}$,

$$
\left\langle h_{n}, h_{m}\right\rangle_{\mathcal{H}}=\frac{\nu(\mathcal{X})^{2}}{\lambda_{k}^{2} n m} \sum_{i=1}^{n} \sum_{j=1}^{m} \psi_{k}\left(\mathbf{t}_{i}\right) \psi_{k}\left(\mathbf{t}_{j}\right) K\left(\mathbf{t}_{i}, \mathbf{t}_{j}\right) .
$$

## Proof of Mercer's Theorem (2/6)

## For any $k \geq 1$ such that $\lambda_{k}>0, \psi_{k} \in \mathcal{H}$ (cont.)

Therefore,

$$
\lim _{n, m \rightarrow+\infty}\left\langle h_{n}, h_{m}\right\rangle_{\mathcal{H}}=\frac{1}{\lambda_{k}^{2}} \iint K\left(\mathbf{t}, \mathbf{t}^{\prime}\right) \psi_{k}(\mathbf{t}) \psi_{k}\left(\mathbf{t}^{\prime}\right) d \nu(\mathbf{t}) d \nu\left(\mathbf{t}^{\prime}\right):=R,
$$

and
$\left\|h_{n}-h_{m}\right\|_{\mathcal{H}}^{2}=\left\langle h_{n}, h_{n}\right\rangle_{\mathcal{H}}+\left\langle h_{m}, h_{m}\right\rangle_{\mathcal{H}}-2\left\langle h_{n}, h_{m}\right\rangle_{\mathcal{H}} \xrightarrow{n, m \rightarrow \infty} R+R-2 R=0$.
$\left(h_{n}\right)_{n \in \mathbb{N}}$ is therefore a Cauchy sequence in $\mathcal{H}$, which converges to a function $h \in \mathcal{H}$. In particular, for any $\mathbf{x} \in \mathcal{X}$,

$$
h(x)=\lim _{n \rightarrow+\infty} h_{n}(\mathbf{x})=\psi_{k}(\mathbf{x})
$$

and finally $\psi_{k}=h \Longrightarrow \psi_{k} \in \mathcal{H}$.

## Proof of Mercer's Theorem (3/6)

$\left\{\sqrt{\lambda_{k}} \psi_{k}: \lambda_{k}>0\right\}$ in an orthonormal system (ONS) of $\mathcal{H}$ Let $i, j \geq 1$ such that $\lambda_{i}, \lambda_{j}>0$. Then $\sqrt{\lambda_{i}} \psi_{i}, \sqrt{\lambda_{j}} \psi_{j} \in \mathcal{H}$ and

$$
\begin{aligned}
\left\langle\sqrt{\lambda_{i}} \psi_{i}, \sqrt{\lambda_{j}} \psi_{j}\right\rangle_{\mathcal{H}} & =\left\langle\frac{1}{\sqrt{\lambda_{i}}} \int K_{\mathbf{t}} \psi_{i}(\mathbf{t}) d \nu(\mathbf{t}), \psi_{i}, \sqrt{\lambda_{j}} \psi_{j}\right\rangle_{\mathcal{H}} \\
& =\sqrt{\frac{\lambda_{j}}{\lambda_{i}}} \int\left\langle K_{\mathbf{t}}, \psi_{j}\right\rangle_{H} \psi_{i}(\mathbf{t}) d \nu(\mathbf{t}) \\
& =\sqrt{\frac{\lambda_{j}}{\lambda_{j}}} \int \psi_{j}(\mathbf{t}) \psi_{i}(\mathbf{t}) d \nu(\mathbf{t}) \\
& =\sqrt{\frac{\lambda_{j}}{\lambda_{i}}}\left\langle\psi_{i}, \psi_{j}\right\rangle_{L_{\nu}^{2}(\mathcal{X})} \\
& =\delta_{i, j} .
\end{aligned}
$$

## Proof of Mercer's Theorem (4/6)

For any $\mathbf{x} \in \mathcal{X}, \sum_{k: \lambda_{k}>0} \lambda_{k} \psi_{k}(x)^{2} \leq C_{K}$
For any $\mathbf{x} \in \mathcal{X}, K_{x} \in \mathcal{H}$ and $\left\|K_{x}\right\|_{\mathcal{H}}^{2}=K(\mathbf{x}, \mathbf{x}) \leq C_{K}$. Therefore, since $\left\{\sqrt{\lambda_{k}} \psi_{k}: \lambda_{k}>0\right\}$ is an ONS of $\mathcal{H}$ :

$$
\begin{aligned}
C_{K} & \geq\left\|K_{x}\right\|_{\mathcal{H}}^{2} \\
& \geq \sum_{k: \lambda_{k}>0}\left\langle K_{\mathrm{x}}, \sqrt{\lambda_{k}} \psi_{k}\right\rangle_{\mathcal{H}}^{2} \\
& =\sum_{k: \lambda_{k}>0} \lambda_{k} \psi_{k}(\mathbf{x})^{2} .
\end{aligned}
$$

## Proof of Mercer's Theorem (5/6)

For any $\mathbf{x} \in \mathcal{X}, \mathbf{t} \rightarrow \sum_{i} \lambda_{i} \psi_{i}(\mathbf{x}) \psi_{i}(\mathbf{t})$ convergences uniformly to a continuous function $g_{x}$
For any fixed $\mathbf{x} \in \mathcal{X}$, we therefore have, for any $\mathbf{t} \in \mathcal{X}$ (restricting the sum to the indices $i \geq 1$ such that $\lambda_{i}>0$ ):

$$
\begin{aligned}
\sum_{i=m}^{m+\ell} \lambda_{i} \psi_{i}(\mathbf{x}) \psi_{i}(\mathbf{t}) & \leq\left(\sum_{i=m}^{m+\ell} \lambda_{i} \psi_{i}(\mathbf{x})^{2}\right)^{\frac{1}{2}}\left(\sum_{i=m}^{m+\ell} \lambda_{i} \psi_{i}(\mathbf{t})^{2}\right)^{\frac{1}{2}} \\
& \leq C_{K}\left(\sum_{i=m}^{m+\ell} \lambda_{i} \psi_{i}(\mathbf{x})^{2}\right)^{\frac{1}{2}}
\end{aligned}
$$

which tends to 0 uniformly in $\mathbf{t} \in \mathcal{X}$. Therefore the series of functions $\mathbf{t} \rightarrow \sum_{i} \lambda_{i} \psi_{i}(\mathbf{x}) \psi_{i}(\mathbf{t})$ is uniformly Cauchy, continuous, and therefore convergences uniformly to a continuous function $g_{x}$.

## Proof of Mercer's Theorem (6/6)

## $K_{\mathrm{x}}=g_{\mathrm{x}}$ in $L_{2}(\nu)$

On the other hand, we can expand $K_{x}$ over the $\operatorname{ONB}\left\{\psi_{k}, k \geq 1\right\}$ of $L_{\nu}^{2}(\mathcal{X}):$

$$
\begin{aligned}
K_{\mathrm{x}} & =\sum_{k \geq 1}\left\langle K_{\mathrm{x}}, \psi_{k}\right\rangle_{L_{\nu}^{2}(\mathcal{X})} \psi_{k} \\
& =\sum_{k \geq 1}\left(L \psi_{k}\right)(\mathbf{x}) \psi_{k} \\
& =\sum_{k \geq 1} \lambda_{k} \psi_{k}(\mathbf{x}) \psi_{k} \\
& =\sum_{k \geq 1: \lambda_{k}>0} \lambda_{k} \psi_{k}(\mathbf{x}) \psi_{k},
\end{aligned}
$$

therefore $K_{\mathrm{x}}=g_{\mathrm{x}}$ in $L_{2}(\nu)$, i.e., $\left\|K_{\mathrm{x}}-g_{\mathrm{x}}\right\|_{L_{2}(\nu)}=0$.

## Proof of Mercer's Theorem (5/5)

## Conclusion

Since $\nu$ in nondegenerate, and both $K_{\mathrm{x}}$ and $g_{\mathrm{x}}$ are continuous, this implies

$$
\forall \mathbf{t} \in \mathcal{X}, \quad K_{\mathbf{x}}(\mathbf{t})=g_{\mathbf{x}}(\mathbf{t})=\sum_{i} \lambda_{i} \psi_{i}(\mathbf{x}) \psi_{i}(\mathbf{t}),
$$

and the convergence is uniform in $\mathcal{X} \times \mathcal{X}$ because $K$ is continuous.

## Mercer kernels as inner products

Let $\ell^{2}$ denote the Hilbert space of real-valued sequences $u=\left(u_{k}\right)_{k \in \mathbb{N}}$ such that $\sum_{k \in \mathbb{N}} u_{k}^{2}<+\infty$, endowed with the inner product $\langle u, v\rangle=\sum_{k \in \mathbb{N}} u_{k} v_{k}$.

## Corollary

The mapping

$$
\left.\begin{array}{rl}
\Phi: \mathcal{X} & \mapsto \ell^{2} \\
& \mathbf{x}
\end{array}\right)\left(\sqrt{\lambda_{k}} \psi_{k}(\mathbf{x})\right)_{k \in \mathbb{N}} .
$$

is well defined, continuous, and satisfies

$$
K(\mathbf{x}, \mathbf{t})=\langle\Phi(\mathbf{x}), \Phi(\mathbf{t})\rangle_{\ell^{2}} .
$$

## Proof of the corollary

- By Mercer theorem we see that for all $\mathbf{x} \in \mathcal{X}, \sum \lambda_{k} \psi_{k}^{2}(\mathbf{x})$ converges to $K(\mathbf{x}, \mathbf{x})<\infty$, therefore $\Phi(\mathbf{x}) \in \ell^{2}$.
- The continuity of $\Phi$ results from:

$$
\begin{aligned}
\|\Phi(\mathbf{x})-\Phi(\mathbf{t})\|_{\ell^{2}}^{2} & =\sum_{k=1}^{\infty} \lambda_{k}\left(\psi_{k}(\mathbf{x})-\psi_{k}(\mathbf{t})\right)^{2} \\
& =K(\mathbf{x}, \mathbf{x})+K(\mathbf{t}, \mathbf{t})-2 K(\mathbf{x}, \mathbf{t})
\end{aligned}
$$

## Summary

- This proof extends the proof valid when $\mathcal{X}$ is finite.
- This is a constructive proof, developed by Mercer (1905).
- The eigensystem ( $\lambda_{k}$ and $\psi_{k}$ ) depend on the choice of the measure $d \nu(\mathbf{x})$ : different $\nu$ 's lead to different feature spaces for a given kernel and a given space $\mathcal{X}$
- Compactness and continuity are required. For instance, for $\mathcal{X}=\mathbb{R}^{d}$, the eigenvalues of:

$$
\int_{\mathcal{X}} K(\mathbf{x}, \mathbf{t}) \psi(\mathbf{t}) d \mathbf{t}=\lambda \psi(\mathbf{x})
$$

are not necessarily countable, Mercer theorem does not hold. Other tools are thus required such as the Fourier transform for shift-invariant kernels.

## Example 1: $[0,1](1 / 6)$

- Consider the unit interval $\mathcal{X}=[0,1]$ endowed with the Lebesgue measure $d \nu(\mathbf{x})=d \mathbf{x}$
- Let a p.d. kernel on $\mathcal{X}$ of the form

$$
K(\mathbf{x}, \mathbf{t})=\kappa(\mathbf{x}-\mathbf{t}),
$$

where $\kappa: \mathbb{R} \rightarrow \mathbb{R}$ is continuous and 1-periodic.

- To write Mercer's expansion we need to find the eigenfunctions of $L_{K}$ by solving

$$
\left(L_{K} \psi\right)(\mathbf{x})=\int_{0}^{1} \kappa(\mathbf{x}-\mathbf{t}) \psi(\mathbf{t}) d \mathbf{t}=\lambda \psi(\mathbf{x})
$$

## Example 1: $[0,1](2 / 6)$

## Lemma

Let $\left(\psi_{n}\right)_{n \in \mathbb{N}}$ be the Fourier ONB of $L^{2}([0,1])$ given by $\psi_{0}(\mathbf{x})=1$ and

$$
\forall n \geq 1, \quad \begin{cases}\psi_{2 n-1}(\mathbf{x}) & =\sqrt{2} \sin (2 \pi n \mathbf{x}) \\ \psi_{2 n}(\mathbf{x}) & =\sqrt{2} \cos (2 \pi n \mathbf{x})\end{cases}
$$

Let the Fourier expansion of $\kappa$ be $e^{a}$

$$
\forall \mathbf{x} \in[0,1], \quad \kappa(\mathbf{x})=\sum_{n=0}^{\infty} \hat{\kappa}_{2 n} \psi_{2 n}(\mathbf{x})
$$

Then for any $n \in \mathbb{N}, \psi_{n}$ is an eigenfunction of $L_{K}$ with eigenvalues $\hat{\kappa}_{0}$ for $\psi_{0}$ and $\hat{\kappa}_{2 n} / \sqrt{2}$ for $\psi_{2 n-1}$ and $\psi_{2 n}$.
${ }^{a} K$ symmetric $\Longrightarrow \kappa$ even $\Longrightarrow \hat{\kappa}_{2 n+1}=0$ for $n \in \mathbb{N}$.

## Example 1: $[0,1](3 / 6)$

Proof sketch:

- $\left(\psi_{n}\right)_{n \in \mathbb{N}}$ is an ONB of $L^{2}([0,1])$ by direct computation of $\int_{0}^{1} \psi_{i}(\mathbf{x}) \psi_{j}(\mathbf{x}) d \mathbf{x}=\delta_{i j}$.
- By trigonometric expansion of $\sin (a+b)$ and $\cos (a+b)$, show that

$$
\begin{cases}\psi_{2 n}(\mathbf{x}-\mathbf{t}) & =\frac{1}{\sqrt{2}}\left[\psi_{2 n}(\mathbf{x}) \psi_{2 n}(\mathbf{t})+\psi_{2 n-1}(\mathbf{x}) \psi_{2 n-1}(\mathbf{t})\right] \\ \psi_{2 n-1}(\mathbf{x}-\mathbf{t}) & =\frac{1}{\sqrt{2}}\left[\psi_{2 n-1}(\mathbf{x}) \psi_{2 n}(\mathbf{t})-\psi_{2 n}(\mathbf{x}) \psi_{2 n-1}(\mathbf{t})\right]\end{cases}
$$

- Then direct computation of $L_{K} \psi_{i}$, e.g.,

$$
\begin{aligned}
L_{K} \psi_{2 n}(\mathbf{x}) & =\sum_{\ell=0}^{\infty} \hat{\kappa}_{2 \ell} \int_{0}^{1} \psi_{2 \ell}(\mathbf{x}-\mathbf{t}) \psi_{2 n}(\mathbf{t}) d \mathbf{t} \\
& =\sum_{\ell=0}^{\infty} \frac{\hat{\kappa}_{2 \ell}}{\sqrt{2}} \int_{0}^{1}\left[\psi_{2 \ell}(\mathbf{x}) \psi_{2 \ell}(\mathbf{t})+\psi_{2 \ell-1}(\mathbf{x}) \psi_{2 \ell-1}(\mathbf{t})\right] \psi_{2 n}(\mathbf{t}) d \mathbf{t} \\
& =\sum_{\ell=0}^{\infty} \frac{\hat{\kappa}_{2 \ell}}{\sqrt{2}} \psi_{2 \ell}(\mathbf{x}) \delta_{n \ell}=\frac{\hat{\kappa}_{2 n}}{\sqrt{2}} \psi_{2 n}(\mathbf{x}) .
\end{aligned}
$$

## Example 1: $[0,1](4 / 6)$

Remark: Mercer's theorem is obviously correct. All $\psi_{k}$ 's are continuous, and for any $\mathbf{x}, \mathbf{t} \in[0,1]$ the Mercer expansion of the kernel is:

$$
\begin{align*}
K(\mathbf{x}, \mathbf{t}) & =\hat{\kappa}_{0}+\sum_{n=1}^{\infty} \frac{\hat{\kappa}_{2 n}}{\sqrt{2}}\left[\psi_{2 n-1}(\mathbf{x}) \psi_{2 n-1}(\mathbf{t})+\psi_{2 n}(\mathbf{x}) \psi_{2 n}(\mathbf{t})\right] \\
& =\sum_{n=0}^{\infty} \hat{\kappa}_{2 n} \psi_{2 n}(\mathbf{x}-\mathbf{t})  \tag{3}\\
& =\kappa(\mathbf{x}-\mathbf{t})
\end{align*}
$$

with absolute and uniform convergence (because $\kappa$ is continuous).

## Example 1: $[0,1](5 / 6)$

## Example: polynomial decay of eigenvalues

For any $\beta \in \mathbb{N}^{*}$, let

$$
\begin{cases}\hat{\kappa}_{0} & =0 \\ \hat{\kappa}_{2 n} & =\sqrt{2} n^{-2 \beta} \text { for } n \geq 1\end{cases}
$$

Then the corresponding kernel is

$$
\forall \mathbf{x}, \mathbf{t} \in[0,1], \quad K(\mathbf{x}, \mathbf{t})=\frac{1}{(2 \beta)!} B_{2 \beta}(\mathbf{x}-\mathbf{t}-\lfloor\mathbf{x}-\mathbf{t}\rfloor),
$$

where $B_{2 \beta}$ is the (2 2 )-th Bernoulli polynomial ${ }^{\text {a }}$, e.g.,

$$
B_{2}(x)=x^{2}-x+1 / 6, \quad B_{4}(x)=x^{4}-2 x^{3}+x^{2}-1 / 30, \ldots
$$

[^0]Proof left as exercice (check Fourier expansion of Bernoulli polynomials).

## Example 1: $[0,1](6 / 6)$

## Example: exponential decay of eigenvalues

For any $\rho \in \mathbb{R}_{+}$, let

$$
\begin{cases}\hat{\kappa}_{0} & =0 \\ \hat{\kappa}_{2 n} & =e^{-\rho n} \text { for } n \geq 1\end{cases}
$$

Then the corresponding kernel is

$$
\forall \mathbf{x}, \mathbf{t} \in[0,1], \quad K(\mathbf{x}, \mathbf{t})=\frac{\sqrt{2} e^{\rho} \cos (2 \pi(\mathbf{x}-\mathbf{t}))-1}{e^{2 \rho}-2 e^{\rho} \cos (2 \pi(\mathbf{x}-\mathbf{t}))+1} .
$$

Proof left as exercice (or check Bach, 2013, p.21).

## Example 2: $S^{d-1}(1 / 6)$

- Consider the unit sphere in $\mathbb{R}^{d}$ :

$$
\mathcal{X}=S^{d-1}=\left\{\mathbf{x} \in \mathbb{R}^{d}:\|\mathbf{x}\|=1\right\}
$$

- Let $\nu$ be the Lebesgue measure on $S^{d-1}$. Note that:

$$
\nu\left(S^{d-1}\right)=\frac{2 \pi^{\frac{d}{2}}}{\Gamma\left(\frac{d}{2}\right)}
$$

## Example 2: $S^{d-1}(2 / 6)$

- Let a p.d. kernel on $S^{d-1}$ of the form:

$$
K(\mathbf{x}, \mathbf{t})=\varphi\left(\mathbf{x}^{\top} \mathbf{t}\right)
$$

where $\varphi:[-1,1] \rightarrow \mathbb{R}$ is continuous.

- To write Mercer's expansion we need to find the eigenfunctions by solving

$$
\int_{S^{d-1}} \varphi\left(\mathbf{x}^{\top} \mathbf{t}\right) \psi(\mathbf{t}) d \nu(\mathbf{t})=\lambda \psi(\mathbf{x})
$$

- For that purpose study polynomials that solve the Laplace equation:

$$
\Delta f=\frac{\partial^{2} f}{\partial x_{1}^{2}}+\ldots+\frac{\partial^{2} f}{\partial x_{d}^{2}}=0
$$

where $\Delta$ is the Laplacian operator on $\mathbb{R}^{d}$.

## Example 2: $S^{d-1}(3 / 6)$

## Definition (Spherical harmonics)

- A homogeneous polynomial of degree $k \geq 0$ in $\mathbb{R}^{d}$ whose Laplacian vanishes is called a homogeneous harmonic of order $k$.
- A spherical harmonic of order $k$ is a homogeneous harmonic of order $k$ on the unit sphere $S^{d-1}$

The set $\mathcal{Y}_{k}(d)$ of spherical harmonics is a vector space of dimension

$$
N(n, k)=\operatorname{dim}\left(\mathcal{Y}_{k}(d)\right)=\frac{(2 k+d-2)(k+d-3)!}{k!(d-2)!} .
$$

## Example 2: $S^{d-1}(4 / 6)$

Spherical harmonics form the Mercer's eigenfunctions, because:

## Theorem (Funk-Hecke) (e.g., Müller, 1998, p.30)

For any $\mathbf{x} \in S^{d-1}, Y_{k} \in \mathcal{Y}_{k}(d)$ and $\varphi \in C([-1,1])$,

$$
\int_{S^{d-1}} \varphi\left(\mathbf{x}^{\top} \mathbf{t}\right) Y_{k}(\mathbf{t}) d \nu(\mathbf{t})=\lambda_{k} Y_{k}(\mathbf{x})
$$

where

$$
\lambda_{k}=\nu\left(S^{d-2}\right) \int_{-1}^{1} \varphi(t) P_{k}(d ; t)\left(1-t^{2}\right)^{\frac{d-3}{2}} d t
$$

and $P_{k}(d ; t)$ is the Legendre polynomial of degree $k$ in dimension $d$. When $\varphi \in C^{k}([-1,1])$ we have Rodrigues rule (Müller, 1998, p.23):

$$
\lambda_{k}=\nu\left(S^{d-2}\right) \frac{\Gamma\left(\frac{d-1}{2}\right)}{2^{k} \Gamma\left(k+\frac{d-1}{2}\right)} \int_{-1}^{1} \varphi^{(k)}(t)\left(1-t^{2}\right)^{k+\frac{d-3}{2}} d t
$$

## Example 2: $S^{d-1}(5 / 6)$

- For any $k \geq 0$, let $\left\{Y_{k, j}(d ; \mathbf{x})\right\}_{j=1}^{N(d ; k)}$ an orthonormal basis of $\mathcal{Y}_{k}(d)$
- Spherical harmonics $\left\{\left\{Y_{k, j}(d ; \mathbf{x})\right\}_{j=1}^{N(d ; k)}\right\}_{k=0}^{\infty}$ form an orthonormal basis for $L^{2}\left(S^{d-1}\right)$
- Therefore, for any kernel $K(\mathbf{x}, \mathbf{t})=\varphi\left(\mathbf{x}^{\top} \mathbf{t}\right)$ on $S^{d-1}$ the Mercer eigenvalues are exactly the $\lambda_{k}$ 's, with corresponding orthonormal eigenfunctions $\left\{Y_{k, j}(d ; \mathbf{x})\right\}_{j=1}^{N(d ; k)}$.
- Note that eigenfunctions are the same for different $\varphi$ 's, only the eigenvalues change

## Example 2: $S^{d-1}(6 / 6)$

- Take $d=2$ and $K(\mathbf{x}, \mathbf{t})=\left(1+\mathbf{x}^{\top} \mathbf{t}\right)^{2}$ for $\mathbf{x}, \mathbf{t} \in S^{1}$
- Using Rodrigeus rule we get 3 nonzero eigenvalues:

$$
\lambda_{0}=3 \pi, \quad \lambda_{1}=2 \pi, \quad \lambda_{2}=\frac{\pi}{2}
$$

with multiplicities 1,2 and 2

- Corresponding eigenfunctions:

$$
\left(\frac{1}{\sqrt{2 \pi}}, \frac{x_{1}}{\sqrt{\pi}}, \frac{x_{2}}{\sqrt{\pi}}, \frac{x_{1} x_{2}}{\sqrt{\pi}}, \frac{x_{1}^{2}-x_{2}^{2}}{\sqrt{\pi}}\right)
$$

- The resulting Mercer feature map is

$$
\Phi(\mathbf{x})=\left(\sqrt{\frac{3}{2}}, \sqrt{2} x_{1}, \sqrt{2} x_{2}, \sqrt{2} x_{1} x_{2}, \frac{x_{1}^{2}-x_{2}^{2}}{\sqrt{2}}\right)
$$

- Obviously, $\Phi(\mathbf{x})^{\top} \Phi(\mathbf{t})=K(\mathbf{x}, \mathbf{t})$ for $\mathbf{x}, \mathbf{t} \in S^{1}$ (exercice)

## RKHS of Mercer kernels

- Let $\mathcal{X}$ be a compact metric space, and $K$ a Mercer kernel on $\mathcal{X}$ (symmetric, continuous and positive definite).
- We have expressed a decomposition of the kernel in terms of the eigenfunctions of the linear convolution operator.
- In some cases this provides an intuitive feature space.
- The kernel also has a RKHS, like any p.d. kernel.
- Can we get an intuition of the RKHS norm in terms of the eigenfunctions and eigenvalues of the convolution operator?

## Reminder: expansion of Mercer kernel

## Theorem

Denote by $L_{K}$ the linear operator of $L_{\nu}^{2}(\mathcal{X})$ defined by:

$$
\forall f \in L_{\nu}^{2}(\mathcal{X}),\left(L_{K} f\right)(\mathbf{x})=\int K(\mathbf{x}, \mathbf{t}) f(\mathbf{t}) d \nu(\mathbf{t})
$$

Let $\left(\lambda_{1}, \lambda_{2}, \ldots\right)$ denote the eigenvalues of $L_{K}$ in decreasing order, and $\left(\psi_{1}, \psi_{2}, \ldots\right)$ the corresponding eigenfunctions. Then it holds that for any $\mathbf{x}, \mathbf{y} \in \mathcal{X}$ :

$$
K(\mathbf{x}, \mathbf{y})=\sum_{k=1}^{\infty} \lambda_{k} \psi_{k}(\mathbf{x}) \psi_{k}(\mathbf{y})=\langle\Phi(\mathbf{x}), \Phi(\mathbf{y})\rangle_{\ell^{2}}
$$

with $\Phi: \mathcal{X} \mapsto \ell^{2}$ defined par $\Phi(\mathbf{x})=\left(\sqrt{\lambda_{k}} \psi_{k}(\mathbf{x})\right)_{k \in \mathbb{N}}$.

## RKHS construction

## Theorem

Assuming that all eigenvalues are positive, the RKHS is the Hilbert space:

$$
\mathcal{H}=\left\{f=\sum_{i=1}^{\infty} a_{i} \psi_{i}, \quad \text { with } \sum_{k=1}^{\infty} \frac{a_{k}^{2}}{\lambda_{k}}<\infty\right\}
$$

endowed with the inner product:

$$
\langle f, g\rangle_{\mathcal{H}}=\sum_{k=1}^{\infty} \frac{a_{k} b_{k}}{\lambda_{k}}, \quad \text { for } f=\sum_{k} a_{k} \psi_{k}, g=\sum_{k} b_{k} \psi_{k} .
$$

## Remark

If some eigenvalues are equal to zero, then the result and the proof remain valid on the subspace spanned by the eigenfunctions with positive eigenvalues.

## Proof (1/6)

## Sketch

In order to show that $\mathcal{H}$ is the RKHS of the kernel $K$ we need to show that:
(1) it is a Hilbert space of functions from $\mathcal{X}$ to $\mathbb{R}$,
(2) for any $\mathbf{x} \in \mathcal{X}, K_{x} \in \mathcal{H}$,
(3) for any $\mathbf{x} \in \mathcal{X}$ and $f \in \mathcal{H}, f(\mathbf{x})=\left\langle f, K_{x}\right\rangle_{\mathcal{H}}$.

## Proof (2/6)

## $\mathcal{H}$ is a Hilbert space

Indeed the function:

$$
\begin{aligned}
L_{K}^{\frac{1}{2}}: L_{\nu}^{2}(\mathcal{X}) & \rightarrow \mathcal{H} \\
\qquad \sum_{i=1}^{\infty} a_{i} \psi_{i} & \mapsto \sum_{i=1}^{\infty} a_{i} \sqrt{\lambda_{i}} \psi_{i}
\end{aligned}
$$

is an isomorphism, therefore $\mathcal{H}$ is a Hilbert space, like $L_{\nu}^{2}(\mathcal{X})$.

## Proof $(3 / 6)$

## $\mathcal{H}$ is a space of continuous functions

For any $f=\sum_{i=1}^{\infty} a_{i} \psi_{i} \in \mathcal{H}$, and $\mathbf{x} \in \mathcal{X}$, we have (if $f(x)$ makes sense):

$$
\begin{aligned}
|f(\mathbf{x})| & =\left|\sum_{i=1}^{\infty} a_{i} \psi_{i}(\mathbf{x})\right|=\left|\sum_{i=1}^{\infty} \frac{a_{i}}{\sqrt{\lambda_{i}}} \sqrt{\lambda_{i}} \psi_{i}(\mathbf{x})\right| \\
& \leq\left(\sum_{i=1}^{\infty} \frac{a_{i}^{2}}{\lambda_{i}}\right)^{\frac{1}{2}} \cdot\left(\sum_{i=1}^{\infty} \lambda_{i} \psi_{i}(\mathbf{x})^{2}\right)^{\frac{1}{2}} \\
& =\|f\|_{\mathcal{H}} K(\mathbf{x}, \mathbf{x})^{\frac{1}{2}} \\
& =\|f\|_{\mathcal{H}} \sqrt{C_{K}}
\end{aligned}
$$

Therefore convergence in $\|.\|_{\mathcal{H}}$ implies uniform convergence for functions.

## Proof (4/6)

## $\mathcal{H}$ is a space of continuous functions (cont.)

Let now $f_{n}=\sum_{i=1}^{n} a_{i} \psi_{i} \in \mathcal{H}$. The functions $\psi_{i}$ are continuous functions, therefore $f_{n}$ is also continuous, for all $n$. The $f_{n}$ 's are convergent in $\mathcal{H}$, therefore also in the (complete) space of continuous functions endowed with the uniform norm.
Let $f_{c}$ the continuous limit function. Then $f_{c} \in L_{\nu}^{2}(\mathcal{X})$ and

$$
\left\|f_{n}-f_{c}\right\|_{L_{\nu}^{2}(\mathcal{X})} \underset{n \rightarrow \infty}{\rightarrow} 0
$$

On the other hand,

$$
\left\|f-f_{n}\right\|_{L_{\nu}^{2}(\mathcal{X})} \leq \lambda_{1}\left\|f-f_{n}\right\|_{\mathcal{H}} \underset{n \rightarrow \infty}{\rightarrow} 0
$$

therefore $f=f_{c}$. $\square$

## Proof (5/6)

## $K_{x} \in \mathcal{H}$

For any $\mathbf{x} \in \mathcal{X}$ let, for all $i, a_{i}=\lambda_{i} \psi_{i}(\mathbf{x})$. We have:

$$
\sum_{i=1}^{\infty} \frac{a_{i}^{2}}{\lambda_{i}}=\sum_{i=1}^{\infty} \lambda_{i} \psi_{i}(\mathbf{x})^{2}=K(\mathbf{x}, \mathbf{x})<\infty
$$

therefore $\varphi_{x}:=\sum_{i=1}^{\infty} a_{i} \psi_{i} \in \mathcal{H}$. As seen earlier the convergence in $\mathcal{H}$ implies pointwise convergence, therefore for any $\mathbf{t} \in \mathcal{X}$ :

$$
\varphi_{x}(\mathbf{t})=\sum_{i=1}^{\infty} a_{i} \psi_{i}(\mathbf{t})=\sum_{i=1}^{\infty} \lambda_{i} \psi_{i}(\mathbf{x}) \psi_{i}(\mathbf{t})=K(\mathbf{x}, \mathbf{t})
$$

therefore $\varphi_{x}=K_{x} \in \mathcal{H}$.

## Proof $(6 / 6)$

$f(\mathbf{x})=\left\langle f, K_{x}\right\rangle_{\mathcal{H}}$
Let $f=\sum_{i=1}^{\infty} a_{i} \psi_{i} \in \mathcal{H}$, et $\mathbf{x} \in \mathcal{X}$. We have seen that:

$$
K_{x}=\sum_{i=1}^{\infty} \lambda_{i} \psi_{i}(\mathbf{x}) \psi_{i}
$$

therefore:

$$
\left\langle f, K_{x}\right\rangle_{\mathcal{H}}=\sum_{i=1}^{\infty} \frac{\lambda_{i} \psi_{i}(\mathbf{x}) a_{i}}{\lambda_{i}}=\sum_{i=1}^{\infty} a_{i} \psi_{i}(\mathbf{x})=f(\mathbf{x})
$$

which concludes the proof. $\square$

## Remarks

- Although $\mathcal{H}$ was built from the eigenfunctions of $L_{K}$, which depend on the choice of the measure $d \nu(\mathbf{x})$, we know by uniqueness of the RKHS that $\mathcal{H}$ is independant of $\nu$ and $L_{K}$.
- Mercer theorem provides a concrete way to build the RKHS, by taking linear combinations of the eigenfunctions of $L_{K}$ (with adequately chosen weights).
- The eigenfunctions $\left(\psi_{i}\right)_{i \in \mathbb{N}}$ form an orthogonal basis of the RKHS:

$$
\left\langle\psi_{i}, \psi_{j}\right\rangle_{\mathcal{H}}=0 \quad \text { si } i \neq j, \quad\left\|\psi_{i}\right\|_{\mathcal{H}}=\frac{1}{\sqrt{\lambda_{i}}}
$$

The RKHS is a well-defined ellipsoid with axes given by the eigenfunctions.

Summary

## Example: Sobolev space of periodic functions on $[0,1]$

## Corollary

For $\beta \in \mathbb{N}_{*}$, let the Mercer kernel with polynomially decaying eigenvalues:

$$
\forall \mathbf{x}, \mathbf{t} \in[0,1], \quad K(\mathbf{x}, \mathbf{t})=\frac{1}{(2 \beta)!} B_{2 \beta}(\mathbf{x}-\mathbf{t}-\lfloor\mathbf{x}-\mathbf{t}\rfloor),
$$

where $B_{2 \beta}$ is the $(2 \beta)$-th Bernoulli polynomial. Then the RKHS is the set of functions $f:[0,1] \rightarrow \mathbb{R}$ whose Fourier coefficients satisfy:

$$
\|f\|_{\mathcal{H}}^{2}:=\sum_{n=1}^{\infty}\left(\hat{f}_{2 n-1}^{2}+\hat{f}_{2 n}^{2}\right) n^{2 \beta}<+\infty
$$

This is the Sobolev space of functions $f$ such that $f^{(i)}$ is absolutely continuous and $f^{(i)}(0)=f^{(i)}(1)$, for $i=0, \ldots, \beta-1$, and

$$
\|f\|_{\mathcal{H}}^{2}=\pi^{-2 \beta} \int_{0}^{1}\left(f^{(\beta)}(\mathbf{x})\right)^{2} d \mathbf{x}
$$

## Proof sketch

- The characterization of the RKHS in terms of Fourier coefficients is a direct application of the previous result, noting that the Fourier basis is an ONB of eigenfunctions of $L_{K}$, and that the corresponding eigenvalues are $n^{-2 \beta}$.
- For the characterization as a Sobolev space, we use Parceval equality to rewrite the Sobolev norm as the $\ell_{2}$ norm of the Fourier coefficients of $f^{(\beta)}$, which are (roughly) the Fourier coefficients of $f$ multiplied by $n^{\beta}$. For details, see Tsybakov (2004, Proposition 1.14).

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Green kernels
- Mercer kernels
- Convergence rates of KRR for Mercer kernels
- Shift-invariant kernels
- Generalization to semigroups
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Isomorphism betwwen $\mathcal{H}$ and $L_{\nu}^{2}(\mathcal{X})$

- We saw that

$$
\begin{aligned}
L_{K}^{\frac{1}{2}}: L_{\nu}^{2}(\mathcal{X}) & \rightarrow \mathcal{H} \\
\qquad \sum_{i=1}^{\infty} a_{i} \psi_{i} & \mapsto \sum_{i=1}^{\infty} a_{i} \sqrt{\lambda_{i}} \psi_{i}
\end{aligned}
$$

is an isomorphism betwwen $\mathcal{H}$ and $L_{\nu}^{2}(\mathcal{X})$, i.e.,

$$
\forall f \in L_{\nu}^{2}(\mathcal{X}), \quad\|f\|_{L_{\nu}^{2}(\mathcal{X})}=\left\|L_{K}^{\frac{1}{2}} f\right\|_{\mathcal{H}}
$$

and conversely,

$$
\forall f \in \mathcal{H}, \quad\|f\|_{\mathcal{H}}=\left\|L_{K}^{-\frac{1}{2}} f\right\|_{L_{\nu}^{2}(\mathcal{X})}
$$

- This can be useful to compute $L_{\nu}^{2}(\mathcal{X})$ norms using RKHS theory, e.g., to study the performance of kernel ridge regression (KRR)

## Remember KRR

- Given $\left(\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right) \in \mathcal{X}^{n}$ and $\left(y_{1}, \ldots, y_{n}\right) \in \mathbb{R}^{n}$, KRR solves for any $\lambda>0$ :

$$
\hat{f}_{\lambda}=\underset{f \in \mathcal{H}}{\arg \min } \frac{1}{n} \sum_{i=1}^{n}\left(y_{i}-f\left(\mathbf{x}_{i}\right)\right)^{2}+\lambda\|f\|_{\mathcal{H}}^{2}
$$

- The solution is

$$
\hat{f}_{\lambda}(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right), \text { where } \boldsymbol{\alpha}=(\mathbf{K}+\lambda n \mathbf{I})^{-1} \mathbf{y}
$$

## Model

- Let $K$ be a Mercer kernel over the compact set $\mathcal{X}$ and nondegenerate probability measure $\nu$ (i.e., $\nu(\mathcal{X})=1$ ). Let $\lambda_{1} \geq \lambda_{2} \geq \ldots \geq 0$ be the eigenvalues of $L_{K},\left\{\psi_{i}, i \geq 1\right\}$ the eigenvectors, and $\left\{\varphi_{i}=\sqrt{\lambda_{i}} \psi_{i}, i \geq 1\right\}$ an ONB of $\mathcal{H}$.
- Let $(X, Y)$ be random variables with distribution $P$, such that

## $X \in \mathcal{X}$ has distribution $\nu$

and

$$
Y=f^{*}(X)+\epsilon \quad \text { where } \quad f^{*} \in \mathcal{H} \quad \text { and } \quad \epsilon \sim \mathcal{N}\left(0, \sigma^{2}\right) .
$$

- We assume $\left(\mathbf{x}_{i}, y_{i}\right)_{i=1, \ldots, n}$ are i.i.d. realizations of $(X, Y)$.
- We want to estimate the performance of KRR in terms of mean squared error:

$$
\operatorname{MSE}\left(\hat{f}_{\lambda}\right)=\mathbb{E}\left(Y-\hat{f}_{\lambda}(X)\right)^{2}
$$

## Decomposition of the MSE

## Lemma

Let $\beta^{*} \in \ell^{2}$ such that $f^{*}=\sum_{i \geq 1} \beta_{i}^{*} \varphi_{i}$, let $\Phi_{N}$ the $n \times \infty$ matrix given by $\Phi_{n}=\left(\varphi_{j}\left(\mathbf{x}_{i}\right)\right)_{1 \leq i \leq n ; 1 \leq j<+\infty}$. and $\mathcal{T}: \ell_{2} \rightarrow \ell_{2}$ be the diagonal operator $\mathcal{T}\left(a_{1}, a_{2}, \ldots\right)=\left(\lambda_{1} a_{1}, \lambda_{2} a_{2}, \ldots\right)$.
Then it holds

$$
\operatorname{MSE}\left(\hat{f}_{\lambda}\right)-\operatorname{MSE}\left(f^{*}\right)=B_{\lambda}+V_{\lambda},
$$

where

$$
\begin{aligned}
& B_{\lambda}=\mathbb{E}\left\|\mathcal{T}^{\frac{1}{2}}\left(\mathbf{I}-\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{I}\right)^{-1} \Phi_{n}^{\top} \Phi_{n}\right) \boldsymbol{\beta}^{*}\right\|_{\ell^{2}}^{2} \\
& V_{\lambda}=\mathbb{E}\left\|\mathcal{T}^{\frac{1}{2}}\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{I}\right)^{-1} \Phi_{n}^{\top} \varepsilon\right\|_{\ell^{2}}^{2}
\end{aligned}
$$

This corresponds to a classical decomposition of excess MSE as "bias + variance". Note that $B_{\lambda}$ increases with $\lambda$, but $V_{\lambda}$ decreases with $\lambda$.

## Decomposition of the MSE: Proof $(1 / 5)$

- Since $\epsilon$ is independent of $X$ and $\hat{f}_{\lambda}$, and $\mathbb{E} \epsilon=0$ we have

$$
\begin{aligned}
\operatorname{MSE}\left(\hat{f}_{\lambda}\right) & =\mathbb{E}\left(f^{*}(X)-\hat{f}_{\lambda}(X)+\epsilon\right)^{2} \\
& =\mathbb{E}\left(f^{*}(X)-\hat{f}_{\lambda}(X)\right)^{2}+\mathbb{E} \epsilon^{2} \\
& =\mathbb{E}\left\|f^{*}-\hat{f}_{\lambda}\right\|_{L_{\nu}^{2}(\mathcal{X})}^{2}+\operatorname{MSE}\left(f^{*}\right) .
\end{aligned}
$$

- Using the isometry between $L_{\nu}^{2}(\mathcal{X})$ and $\mathcal{H}$, we obtain

$$
\operatorname{MSE}\left(\hat{f}_{\lambda}\right)-\operatorname{MSE}\left(f^{*}\right)=\mathbb{E}\left\|L_{K}^{\frac{1}{2}}\left(f^{*}-\hat{f}_{\lambda}\right)\right\|_{\mathcal{H}}^{2} .
$$

## Decomposition of the MSE: Proof $(2 / 5)$

- $\left\{\varphi_{i}=\sqrt{\lambda_{i}} \psi_{i}\right\}, i \geq 1$ is an ONB of $\mathcal{H}$, we can define the linear isomorphism:

$$
\begin{aligned}
& e: \mathcal{H} \rightarrow \ell^{2} \\
& \qquad f=\sum_{i \geq 1} a_{i} \varphi_{i} \mapsto\left(a_{1}, a_{2} \ldots\right)^{\top}
\end{aligned}
$$

- In other words,

$$
e(f)_{i}=\left\langle f, \varphi_{i}\right\rangle_{\mathcal{H}} .
$$

- In particular, for any $\mathbf{x} \in \mathcal{X}$,

$$
e\left(K_{\mathbf{x}}\right)=\left(\varphi_{1}(\mathbf{x}), \varphi_{2}(\mathbf{x}), \ldots\right)^{\tau}
$$

- In that base $L_{K}$ is a diagonal operator $\mathcal{T}=\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \ldots\right)$, i.e.,

$$
\forall f=\sum_{i \geq 1} a_{i} \varphi_{i} \in \mathcal{H}, \quad e\left(L_{K} f\right)=\mathcal{T} e(f)=\left(\lambda_{1} a_{1}, \lambda_{2} a_{2}, \ldots\right)^{\top}
$$

## Decomposition of the MSE: Proof $(3 / 5)$

- Let $\Phi_{n}=\left(e\left(K_{\mathbf{x}_{1}}\right), \ldots, e\left(K_{\mathbf{x}_{n}}\right)\right)^{\top}$, i.e.,

$$
\Phi_{n}=\left(\varphi_{j}\left(\mathbf{x}_{i}\right)\right)_{1 \leq i \leq n ; 1 \leq j<+\infty} .
$$

- Then $\hat{f}_{\lambda}=\sum_{i=1}^{n} \alpha_{i} K_{\mathbf{x}_{i}}$ translates to

$$
e\left(\hat{f}_{\lambda}\right)=\sum_{i=1}^{n} \alpha_{i} e\left(K_{x_{i}}\right)=\Phi_{n}^{\top} \boldsymbol{\alpha}
$$

- Notice that

$$
\left[\Phi_{n} \Phi_{n}^{\top}\right]_{i j}=\left\langle e\left(K_{\mathbf{x}_{i}}\right), e\left(K_{\mathbf{x}_{j}}\right)\right\rangle_{\ell^{2}}=\left\langle K_{\mathbf{x}_{i}}, K_{\mathbf{x}_{j}}\right\rangle_{\mathcal{H}}=K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right),
$$

so $\Phi_{n} \Phi_{n}^{\top}=\mathbf{K}$ and $\boldsymbol{\alpha}=(\mathbf{K}+\lambda n \mathbf{I})^{-1} \mathbf{y}$ translates to

$$
\boldsymbol{\alpha}=\left(\Phi_{n} \Phi_{n}^{\top}+\lambda n \mathbf{I}\right)^{-1} \mathbf{y} .
$$

- Putting it all together, and using the matrix inversion lemma:

$$
e\left(\hat{f}_{\lambda}\right)=\Phi_{n}^{\top}\left(\Phi_{n} \Phi_{n}^{\top}+\lambda n \mathbf{I}\right)^{-1} \mathbf{y}=\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{I}\right)^{-1} \Phi_{n}^{\top} \mathbf{y}
$$

## Decomposition of the MSE: Proof $(4 / 5)$

- Let $\boldsymbol{\beta}^{*}=\left(\beta_{1}^{*}, \beta_{2}^{*}, \ldots\right)^{\top}=e\left(f^{*}\right)$, i.e.,

$$
f^{*}=\sum_{i \geq 1} \beta_{i}^{*} \varphi_{i}
$$

In particular, for any $\mathbf{x} \in \mathcal{X}$,

$$
f^{*}(\mathbf{x})=\left\langle f^{*}, K_{\mathbf{x}}\right\rangle_{\mathcal{H}}=\left\langle\boldsymbol{\beta}^{*}, e\left(K_{\mathbf{x}}\right)\right\rangle_{\ell^{2}} .
$$

- Then $y_{i}=f^{*}\left(\mathbf{x}_{i}\right)+\epsilon_{i}$ for $i=1, \ldots, n$ translates to

$$
\mathbf{y}=\Phi_{n} \boldsymbol{\beta}^{*}+\varepsilon
$$

where $\varepsilon=\left(\epsilon_{1}, \ldots, \epsilon_{n}\right)^{\top}$.

## Decomposition of the MSE: Proof $(5 / 5)$

- This gives

$$
\begin{aligned}
& e\left(f^{*}-\hat{f}_{\lambda}\right)=\boldsymbol{\beta}^{*}-\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{l}\right)^{-1} \Phi_{n}^{\top}\left(\Phi_{n} \boldsymbol{\beta}^{*}+\varepsilon\right) \\
& =\left(\mathbf{I}-\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{l}\right)^{-1} \Phi_{n}^{\top} \Phi_{n}\right) \boldsymbol{\beta}^{*}-\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{l}\right)^{-1} \Phi_{n}^{\top} \varepsilon
\end{aligned}
$$

and therefore, since $\varepsilon$ is independent of $\Phi_{n}$ :

$$
\begin{aligned}
\mathbb{E}\left\|L_{K}^{\frac{1}{2}}\left(f^{*}-\hat{f}_{\lambda}\right)\right\|_{\mathcal{H}}^{2} & =\mathbb{E}\left\|e\left(L_{K}^{\frac{1}{2}}\left(f^{*}-\hat{f}_{\lambda}\right)\right)\right\|_{\ell^{2}}^{2} \\
& \left.=\mathbb{E} \| \mathcal{T}^{\frac{1}{2}} e\left(f^{*}-\hat{f}_{\lambda}\right)\right) \|_{\ell^{2}}^{2} \\
& =\mathbb{E}\left\|\mathcal{T}^{\frac{1}{2}}\left(\mathbf{I}-\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{I}\right)^{-1} \Phi_{n}^{\top} \Phi_{n}\right) \boldsymbol{\beta}^{*}\right\|_{\ell^{2}}^{2} \\
& +\mathbb{E}\left\|\mathcal{T}^{\frac{1}{2}}\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{I}\right)^{-1} \Phi_{n}^{\top} \varepsilon\right\|_{\ell^{2}}^{2} .
\end{aligned}
$$

## Simplification

- $B_{\lambda}$ and $V_{\lambda}$ depend on the data through $\Phi_{n} \Phi_{n}^{\top}$, which is a random operator $\ell^{2} \rightarrow \ell^{2}$.
- For "large $n$ ", we note that, for any $i, j \geq 1$ :

$$
\left[\Phi_{n} \Phi_{n}^{\top}\right]_{i j}=\sum_{k=1}^{n} \varphi_{i}\left(\mathbf{x}_{k}\right) \varphi_{j}\left(\mathbf{x}_{k}\right) \approx n\left\langle\varphi_{i}, \varphi_{j}\right\rangle_{L_{\nu}^{2}(\mathcal{X})}=n \sqrt{\mu_{i} \mu_{j}} \delta_{i j},
$$

SO

$$
\Phi_{n} \Phi_{n}^{\top} \approx n \mathcal{T}
$$

- We now study $B_{\lambda}$ and $V_{\lambda}$ under the approximation " $\Phi_{n} \Phi_{n}^{\top}=n \mathcal{T}$ " (and call $\tilde{B}_{\lambda}$ and $\tilde{V}_{\lambda}$ the corresponding approximations).
- The difference between $B_{\lambda}$ and $\tilde{B}_{\lambda}$ (resp. $V_{\lambda}$ and $\tilde{V}_{\lambda}$ ) can be studied rigorously but will not change much the main results we will get; see, e.g., Dicker et al. (2015) for details.

## Upper bounds on the bias and variance

Theorem
For any $\mathrm{J} \geq 1$,

$$
\tilde{B}_{\lambda} \leq\left(\frac{\lambda^{2}}{\lambda_{J}}+\lambda_{J+1}\right)\left\|f^{*}\right\|_{\mathcal{H}}^{2},
$$

and

$$
\tilde{V}_{\lambda} \leq \frac{\sigma^{2}}{n}\left[J+\frac{\sum_{i=J+1}^{+\infty} \lambda_{i}}{4 \lambda}\right] .
$$

The integer $J$ (and $\lambda$ ) will be optimized later, depending on the assumptions we make on $f^{*}$ and on the decrease of $\lambda_{i}$.

## Proof: bias $(1 / 2)$

- Using $\mathcal{T}=\operatorname{diag}\left(\lambda_{i} ; i \geq 1\right)$ and $\Phi_{n} \Phi_{n}^{\top}=n \mathcal{T}$, we get

$$
\mathcal{T}^{\frac{1}{2}}\left(\mathbf{I}-\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{I}\right)^{-1} \Phi_{n}^{\top} \Phi_{n}\right)=\operatorname{diag}\left(\frac{\lambda \sqrt{\lambda_{i}}}{\lambda+\lambda_{i}} ; i \geq 1\right)
$$

and therefore, for any $J \geq 1$ :

$$
\tilde{B}_{\lambda}=\sum_{i=1}^{J} \frac{\lambda^{2} \lambda_{i}}{\left(\lambda+\lambda_{i}\right)^{2}}\left(\beta_{i}^{*}\right)^{2}+\sum_{i \geq J+1}^{\infty} \frac{\lambda^{2} \lambda_{i}}{\left(\lambda+\lambda_{i}\right)^{2}}\left(\beta_{i}^{*}\right)^{2}
$$

- For the first term, we use the fact that $\frac{\lambda_{i}^{2}}{\left(\lambda+\lambda_{i}\right)^{2}} \leq 1$, and that $\lambda_{i} \geq \lambda_{J}$ for $i \leq J$, to get

$$
\begin{aligned}
& \sum_{i=1}^{J} \frac{\lambda^{2} \lambda_{i}}{\left(\lambda+\lambda_{i}\right)^{2}}\left(\beta_{i}^{*}\right)^{2}=\sum_{i=1}^{J} \frac{\lambda^{2}}{\lambda_{i}} \frac{\lambda_{i}^{2}}{\left(\lambda+\lambda_{i}\right)^{2}}\left(\beta_{i}^{*}\right)^{2} \\
& \leq \frac{\lambda^{2}}{\lambda_{J}} \sum_{i=1}^{J}\left(\beta_{i}^{*}\right)^{2} \leq \frac{\lambda^{2}}{\lambda_{J}}\left\|\boldsymbol{\beta}^{*}\right\|_{\ell^{2}}^{2}
\end{aligned}
$$

## Proof: bias $(2 / 2)$

- For the second term, we use the fact that $\frac{\lambda^{2}}{\left(\lambda+\lambda_{i}\right)^{2}} \leq 1$, and that $\lambda_{i} \leq \lambda_{J+1}$ for $i \geq J+1$, to get

$$
\sum_{i \geq J+1}^{\infty} \frac{\lambda^{2} \lambda_{i}}{\left(\lambda+\lambda_{i}\right)^{2}}\left(\beta_{i}^{*}\right)^{2} \leq \lambda_{J+1} \sum_{i \geq J+1}^{\infty}\left(\beta_{i}^{*}\right)^{2} \leq \lambda_{J+1}\left\|\boldsymbol{\beta}^{*}\right\|_{\ell^{2}}^{2}
$$

- Noting that $\left\|\boldsymbol{\beta}^{*}\right\|_{\ell^{2}}=\left\|f^{*}\right\|_{\mathcal{H}}$, we finally get

$$
\tilde{B}_{\lambda} \leq\left(\frac{\lambda^{2}}{\lambda_{J}}+\lambda_{J+1}\right)\left\|f^{*}\right\|_{\mathcal{H}}^{2}
$$

## Proof: variance (1/2)

Using $\mathcal{T}=\operatorname{diag}\left(\lambda_{i} ; i \geq 1\right), \Phi_{n} \Phi_{n}^{\top}=n \mathcal{T}$ and $\mathbb{E} \varepsilon \varepsilon^{\top}=\sigma^{2} \mathbf{I}$, we get

$$
\begin{aligned}
\tilde{V}_{\lambda} & =\mathbb{E}\left\|\mathcal{T}^{\frac{1}{2}}\left(\Phi_{n}^{\top} \Phi_{n}+\lambda n \mathbf{I}\right)^{-1} \Phi_{n}^{\top} \varepsilon\right\|_{\ell^{2}}^{2} \\
& =\frac{1}{n^{2}} \mathbb{E}\left\|\mathcal{T}^{\frac{1}{2}}(\mathcal{T}+\lambda \mathbf{I})^{-1} \Phi_{n}^{\top} \varepsilon\right\|_{\ell^{2}}^{2} \\
& =\frac{1}{n^{2}} \mathbb{E} \operatorname{Trace}\left[\mathcal{T}^{\frac{1}{2}}(\mathcal{T}+\lambda \mathbf{I})^{-1} \Phi_{n}^{\top} \varepsilon \varepsilon^{\top} \Phi_{n}(\mathcal{T}+\lambda \mathbf{I})^{-1} \mathcal{T}^{\frac{1}{2}}\right] \\
& =\frac{1}{n^{2}} \operatorname{Trace}\left[\mathcal{T}^{\frac{1}{2}}(\mathcal{T}+\lambda \mathbf{I})^{-1} \Phi_{n}^{\top} \mathbb{E}\left(\varepsilon \varepsilon^{\top}\right) \Phi_{n}(\mathcal{T}+\lambda \mathbf{I})^{-1} \mathcal{T}^{\frac{1}{2}}\right] \\
& =\frac{\sigma^{2}}{n} \operatorname{Trace}\left[\mathcal{T}^{\frac{1}{2}}(\mathcal{T}+\lambda \mathbf{I})^{-1} \mathcal{T}(\mathcal{T}+\lambda \mathbf{I})^{-1} \mathcal{T}^{\frac{1}{2}}\right] \\
& =\frac{\sigma^{2}}{n}\left[\sum_{i=1}^{J} \frac{\lambda_{i}^{2}}{\left(\lambda_{i}+\lambda\right)^{2}}+\sum_{i=J+1}^{+\infty} \frac{\lambda_{i}^{2}}{\left(\lambda_{i}+\lambda\right)^{2}}\right] .
\end{aligned}
$$

## Proof: variance $(2 / 2)$

- For the first term, we just use $\frac{\lambda_{i}^{2}}{\left(\lambda_{i}+\lambda\right)^{2}} \leq 1$ to get

$$
\sum_{i=1}^{J} \frac{\lambda_{i}^{2}}{\left(\lambda_{i}+\lambda\right)^{2}} \leq J
$$

- For the second term, we use the fact that $t \rightarrow \frac{t}{(t+\lambda)^{2}}$ reaches its maximum at $t=\lambda$ equal to $\frac{1}{4 \lambda}$, therefore

$$
\sum_{i=J+1}^{+\infty} \frac{\lambda_{i}^{2}}{\left(\lambda_{i}+\lambda\right)^{2}} \leq \frac{\sum_{i=J+1}^{+\infty} \lambda_{i}}{4 \lambda}
$$

- Combining both terms finally gives

$$
\tilde{V}_{\lambda} \leq \frac{\sigma^{2}}{n}\left[J+\frac{\sum_{i=J+1}^{+\infty} \lambda_{i}}{4 \lambda}\right]
$$

## Corollary: rates of convergence of KRR

- Polynomial-decay kernels. Suppose there are constants $C>0$ and $s>1$ such that $0<\lambda_{i} \leq \mathrm{Ci}^{-s}$ for $i=1,2, \ldots$. Let $\lambda=n^{-\frac{s}{s+1}}$.
Then

$$
\tilde{B}_{\lambda}+\tilde{V}_{\lambda} \leq O\left\{\left(\left\|f^{*}\right\|_{\mathcal{H}}^{2}+\sigma^{2}\right) n^{-\frac{s}{s+1}}\right\} .
$$

- Exponential-decay kernels. Suppose there are constants $C>0$ and $\alpha>0$ such that $0<\lambda_{i} \leq C e^{-\alpha i}$ for $i=1,2, \ldots$. Let $\lambda=n^{-1} \log (n)$. Then

$$
\tilde{B}_{\lambda}+\tilde{V}_{\lambda} \leq O\left\{\left(\left\|f^{*}\right\|_{\mathcal{H}}^{2}+\sigma^{2}\right) \frac{\log (n)}{n}\right\}
$$

- Finite rank kernels. Suppose there is $J \geq 1$ such that $\lambda_{J}=\lambda_{J+1}=\ldots=0$. Let $\lambda=n^{-1}$. Then

$$
\tilde{B}_{\lambda}+\tilde{V}_{\lambda} \leq O\left\{\left(\left\|f^{*}\right\|_{\mathcal{H}}^{2}+\sigma^{2}\right) \frac{J}{n}\right\}
$$

## Remarks

- The same result holds for $B_{\lambda}+V_{\lambda}$, see Dicker et al. (2015, corollary $1-4)$. We follow and adapt their proof.
- The constants in the "big- $O$ " notation only depend on the kernel $K$ and the measure $d \nu(\mathbf{x})$.
- The rates are minimax optimal (Caponnetto and De Vito, 2007).
- In particular, for polynomial-decay kernels, $B_{\mathcal{H}}(r) \subset L_{\nu}^{2}(\mathcal{X})$ is a Sobolev space of $q-1$ times absolutely continuous and differentiable functions $f$ with $\left\|f^{q}\right\|_{L_{\nu}^{2}(\mathcal{X})}<+\infty$, for $s=2 q$. We recover the standard optimal convergence rate of nonparametric regression $n^{-\frac{2 q}{2 q+1}}$ (Tsybakov, 2004).
- If we make additional assumptions on $f^{*}$, e.g., not only $\sum_{i \geq 1}\left(\beta_{i}^{*}\right)^{2}$ but also $\sum_{i \geq 1} i^{\tau}\left(\beta_{i}^{*}\right)^{2}$ for $\tau>0$, or $\beta_{i}^{*}=0$ for $i>J$, then we can get faster convergence rate, which are also minimax optimal for the class of functions considered. We say that KRR is adaptive (Caponnetto and De Vito, 2007; Dicker et al., 2015).

## Proof for polynomial-decay kernels $(1 / 3)$

- Let $J$ such that $\lambda_{J+1} \leq \lambda \leq \lambda_{J}$.
- For the bias, we immediately get

$$
\frac{\lambda^{2}}{\lambda_{J}} \leq \lambda \quad \text { and } \quad \lambda_{J+1} \leq \lambda
$$

therefore

$$
\tilde{B}_{\lambda} \leq 2 \lambda\left\|f^{*}\right\|_{\mathcal{H}}^{2}=2 n^{-\frac{s}{s+1}}\left\|f^{*}\right\|_{\mathcal{H}}^{2} .
$$

- For the variance, we need to upper bound $J$ and $\sum_{i \geq J+1} \lambda_{i}$.
- $\lambda \leq \lambda_{J} \leq$ CJ $^{-s}$, therefore

$$
J \leq C^{\frac{1}{s}} \lambda^{-\frac{1}{s}}=C^{\frac{1}{s}} n^{\frac{1}{s+1}}
$$

## Proof for polynomial-decay kernels $(2 / 3)$

- To upper bound the sum, let $J_{0}=\left\lfloor C^{\frac{1}{s}} n^{\frac{1}{s+1}}\right\rfloor+1$. Then:

$$
\begin{aligned}
\sum_{i=J+1}^{+\infty} \lambda_{i} & =\sum_{i=J+1}^{J_{0}} \lambda_{i}+\sum_{i=J_{0}+1}^{+\infty} \lambda_{i} \\
& \leq J_{0} \lambda+C \int_{J_{0}}^{+\infty} t^{-s} d t \\
& \leq J_{0} n^{-\frac{s}{s+1}}+\frac{C}{s-1} J_{0}^{1-s}
\end{aligned}
$$

- Since $J_{0} \leq C^{\frac{1}{s}} n^{\frac{1}{s+1}}+1$ and $1 \leq n^{\frac{1}{s+1}}$,

$$
J_{0} n^{-\frac{s}{s+1}} \leq\left(C^{\frac{1}{s}}+1\right) n^{\frac{1-s}{s+1}}
$$

- Since $J_{0} \geq C^{\frac{1}{s}} n^{\frac{1}{s+1}}$,

$$
\frac{C}{s-1} J_{0}^{1-s} \leq \frac{C^{\frac{1}{s}} n^{\frac{1-s}{s+1}}}{s-1}
$$

## Proof for polynomial-decay kernels $(3 / 3)$

- Therefore the sum is upper bounded by

$$
\sum_{i=J+1}^{+\infty} \lambda_{i} \leq\left(\frac{s}{s-1} C^{\frac{1}{s}}+1\right) n^{\frac{1-s}{s+1}}
$$

- Finally,

$$
\begin{aligned}
\tilde{V}_{\lambda} & =\frac{\sigma^{2}}{n}\left[J+\frac{\sum_{i=J+1}^{+\infty} \lambda_{i}}{4} n^{-\frac{s}{s+1}}\right] \\
& \leq \frac{\sigma^{2}}{n}\left[C^{\frac{1}{s}} n^{\frac{1}{s+1}}+\frac{1}{4}\left(\frac{s}{s-1} C^{\frac{1}{s}}+1\right) n^{\frac{1-s}{s+1}} n^{-\frac{s}{s+1}}\right] \\
& \leq \sigma^{2}\left[C^{\frac{1}{s}}\left(1+\frac{s}{4(s-1)}\right)+\frac{1}{4}\right] n^{\frac{-s}{s+1}} .
\end{aligned}
$$

## Proof sketch for exponential-decay kernels

- We proceed similarly.
- From $\lambda \leq \lambda_{J}$ we deduce $J \leq O(\log (n))$.
- Using $J_{0}=\left\lfloor\alpha^{-1} \log (n)\right\rfloor+1$ we deduce $\sum_{i \geq J+1} \lambda_{i} \leq 0\left(\frac{\log (n)^{2}}{n}\right)$.
- Details left as exercice; see Dicker et al. (2015, corollary 2).

## Proof for finite-rank kernels

- We use a simpler upper bound on $\tilde{B}_{\lambda}$ : using the fact that $\frac{t}{(t+\lambda)^{2}} \leq \frac{1}{4 \lambda}$ for any $t$, and $\lambda_{i}=0$ for $i>J$ :

$$
\tilde{B}_{\lambda} \leq \frac{\lambda}{4}\left\|f^{*}\right\|_{\mathcal{H}}^{2}
$$

- For the variance, our bound simplifies to

$$
\tilde{V}_{\lambda} \leq \frac{\sigma^{2} J}{n}
$$

- Taking $\lambda=n^{-1}$ and summing this inequalities gives the result.

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Green kernels
- Mercer kernels
- Convergence rates of KRR for Mercer kernels
- Shift-invariant kernels
- Generalization to semigroups
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Motivation

- Let us suppose that $\mathcal{X}$ is not compact, for example $\mathcal{X}=\mathbb{R}^{d}$.
- In that case, the eigenvalues of:

$$
\int_{\mathcal{X}} K(\mathbf{x}, \mathbf{t}) \psi(\mathbf{t}) d \nu(\mathbf{t})=\lambda \psi(\mathbf{t})
$$

are not necessarily countable, Mercer theorem does not hold.

- Fourier transforms provide a convenient extension for translation invariant kernels, i.e., kernels of the form $K(\mathbf{x}, \mathbf{y})=\varphi(\mathbf{x}-\mathbf{y})$.
- Harmonic analysis also bring kernels well beyond vector spaces, e.g., groups and semigroups

## Translation invariant kernels on $\mathbb{Z}$

## Definition

A kernel $K: \mathbb{Z} \times \mathbb{Z} \mapsto \mathbb{R}$ is called translation invariant (t.i.), or shift-invariant, if it only depends on the difference between its argument, i.e.:

$$
\forall \mathbf{x}, \mathbf{y} \in \mathbb{Z}, \quad K(\mathbf{x}, \mathbf{y})=a_{\mathrm{x}-\mathbf{y}}
$$

for some sequence $\left\{a_{n}\right\}_{n \in \mathbb{Z}}$. Such a sequence is called positive definite if the corresponding kernel $K$ is p.d.

## Translation invariant kernels on $\mathbb{Z}$

## Definition

A kernel $K: \mathbb{Z} \times \mathbb{Z} \mapsto \mathbb{R}$ is called translation invariant (t.i.), or shift-invariant, if it only depends on the difference between its argument, i.e.:

$$
\forall \mathbf{x}, \mathbf{y} \in \mathbb{Z}, \quad K(\mathbf{x}, \mathbf{y})=a_{\mathrm{x}-\mathbf{y}}
$$

for some sequence $\left\{a_{n}\right\}_{n \in \mathbb{Z}}$. Such a sequence is called positive definite if the corresponding kernel $K$ is p.d.

## Theorem (Herglotz)

A sequence $\left\{a_{n}\right\}_{n \in \mathbb{Z}}$ is p.d. if and only if it is the Fourier-Stieltjes transform of a positive measure $\mu \in M(\mathbb{T})$, the set of finite Borel measures on the torus $[0,2 \pi]$ with 0 and $2 \pi$ identified.

## Fourier-Stieltjes transform on the torus

- Let $\mathbb{T}$ the torus $[0,2 \pi]$ with 0 and $2 \pi$ identified
- $C(\mathbb{T})$ the set of continuous functions on $\mathbb{T}$
- $M(\mathbb{T})$ the finite complex Borel measures ${ }^{2}$ on $\mathbb{T}$
- $M(\mathbb{T})$ can be identified as the dual space $(C(\mathbb{T}))^{*}$ : for any continuous/bounded linear functional $\psi: C(\mathbb{T}) \rightarrow \mathbb{C}$ there exists $\mu \in M(\mathbb{T})$ such that $\psi(f)=\frac{1}{2 \pi} \int_{\mathbb{T}} f(t) \overline{d \mu(t)}$ (Riesz theorem).

## Definition (Fourier-Stieltjes coefficients)

For any $\mu \in M(\mathbb{T})$, the Fourier-Stieltjes coefficients of $\mu$ is the sequence:

$$
\forall n \in \mathbb{Z}, \quad \hat{\mu}(n)=\frac{1}{2 \pi} \int_{\mathbb{T}} e^{-i n t} d \mu(t)
$$

This extends the standard Fourier transform for integrable functions by taking $d \mu(t)=f(t) d t$.

[^1]
## Examples

- Diagonal kernel:

$$
\mu=d t, \quad a_{n}=\hat{\mu}(n)=\frac{1}{2 \pi} \int_{\mathbb{T}} e^{i n t} d t= \begin{cases}1 & \text { if } n=0 \\ 0 & \text { otherwise }\end{cases}
$$

The resulting kernel is $K(\mathbf{x}, \mathbf{t})=\mathbf{1}(\mathbf{x}=\mathbf{t})$.

- Constant kernel: for $C \geq 0$,

$$
\mu=2 \pi C \delta_{0}, \quad a_{n}=\hat{\mu}(n)=C \int_{\mathbb{T}} e^{i n t} \delta_{0}(t)=C
$$

resulting in $K(\mathbf{x}, \mathbf{t})=C$

## Proof of Herglotz's theorem: $\Leftarrow$

If $a_{n}=\hat{\mu}(n)$ for $\mu \in M(\mathbb{T})$ positive, then for any $n \in \mathbb{N}, \mathbf{x}_{1}, \ldots, \mathbf{x}_{n} \in \mathbb{Z}$ and $z_{1}, \ldots, z_{n} \in \mathbb{R}($ or $\mathbb{C})$ :

$$
\begin{aligned}
\sum_{i=1}^{n} \sum_{j=1}^{n} z_{i} \bar{z}_{j} a_{\mathbf{x}_{i}-\mathbf{x}_{j}} & =\frac{1}{2 \pi} \sum_{i=1}^{n} \sum_{j=1}^{n} z_{i} \bar{z}_{j} \int_{\mathbb{T}} e^{-i\left(\mathbf{x}_{i}-\mathbf{x}_{j}\right) t} d \mu(t) \\
& =\frac{1}{2 \pi} \sum_{i=1}^{n} \sum_{j=1}^{n} z_{i} \bar{z}_{j} \int_{\mathbb{T}} e^{-i \mathbf{x}_{i} t} e^{i \mathbf{x}_{j} t} d \mu(t) \\
& =\frac{1}{2 \pi} \int_{\mathbb{T}}\left|\sum_{j=1}^{n} z_{j} e^{-i \mathbf{x}_{j} t}\right|^{2} d \mu(t) \\
& \geq 0
\end{aligned}
$$

## Proof of Herglotz's theorem: $\Rightarrow(1 / 4)$

- Let $\left\{a_{n}\right\}_{n \in \mathbb{Z}}$ a p.d. sequence
- For a given $t \in \mathbb{R}$ and $N \in \mathbb{N}$ let $\left\{z_{n}\right\}_{n \in \mathbb{Z}}$ be

$$
z_{n}= \begin{cases}e^{i n t} & \text { if }|n| \leq N \\ 0 & \text { otherwise }\end{cases}
$$

- Since $\left\{a_{n}\right\}_{n \in \mathbb{Z}}$ is p.d. we get:

$$
\begin{aligned}
0 \leq \sum_{k=-N}^{N} \sum_{I=-N}^{N} a_{k-I z_{k}} \bar{z}_{I} & =\sum_{k=-N}^{N} \sum_{I=-N}^{N} a_{k-I} e^{i(k-I) t} \\
& =\sum_{k=-2 N}^{2 N}(2 N+1-|k|) a_{k} e^{i k t} \\
& =(2 N+1) \underbrace{\sum_{k \in \mathbb{Z}} \max \left(0,1-\frac{|k|}{2 N+1}\right) a_{k} e^{i k t}}_{\sigma_{2 N}(t)}
\end{aligned}
$$

## Proof of Herglotz's theorem: $\Rightarrow(2 / 4)$

- $d \mu_{N}=\sigma_{N}(t) d t$ is a positive measure (for $N$ even) and satisfies

$$
\hat{\mu}_{N}(n)=\frac{1}{2 \pi} \sum_{j=-N}^{N} a_{j}\left(1-\frac{|j|}{N+1}\right) \int_{\mathbb{T}} e^{i(n-j) t}=a_{n} \max \left(0,1-\frac{|n|}{N+1}\right)
$$

- Moreover

$$
\begin{aligned}
\left\|\mu_{N}\right\|_{M(\mathbb{T})} & =\sup _{\|f\|_{\infty} \leq 1} \int_{\mathbb{T}} f(t) \sigma_{N}(t) d t \\
& \left.=\int_{\mathbb{T}} \sigma_{N}(t) d t \quad \text { (take } f=1 \text { because } \sigma_{N}(t) \geq 0\right) \\
& =\sum_{n=-N}^{N} \int_{\mathbb{T}} a_{n}\left(1-\frac{|n|}{N+1}\right) e^{i n t} d t \\
& =a_{0}
\end{aligned}
$$

## Proof of Herglotz's theorem: $\Rightarrow(3 / 4)$

- For any trigonometric polynomial of the form
$P(t)=\sum_{k=-K}^{K} b_{k} e^{i k t}$, with Fourier coefficient $\hat{P}(n)=b_{n}$, we have

$$
\begin{aligned}
\lim _{N \rightarrow+\infty} & \int_{\mathbb{T}} P(t) d \mu_{N}(t) \\
& =\lim _{N \rightarrow+\infty} \sum_{k=-K}^{K} \sum_{n=-N}^{N} \int_{\mathbb{T}} a_{n} b_{k}\left(1-\frac{|n|}{N+1}\right) e^{i(n-k) t} d t \\
& =\sum_{k=-K}^{K} a_{k} b_{k} \lim _{N \rightarrow+\infty}\left(1-\frac{|n|}{N+1}\right) \\
& =\sum_{k=-K}^{K} a_{k} b_{k} \\
& =\sum_{k \in \mathbb{Z}} a_{k} \hat{P}(k)
\end{aligned}
$$

## Proof of Herglotz's theorem: $\Rightarrow(4 / 4)$

- This shows that $\Psi(P)=\sum_{k \in \mathbb{Z}} a_{k} \hat{P}(k)$ is a linear functional over trigonometric polynomials, with norm $\leq a_{0}$
- It can be extended to all continuous functions because trigonometric polynomials are dense in $C(\mathbb{T})$
- By Riesz representation theorem, there exists a measure $\mu \in M(\mathbb{T})$ such that $\|\mu\|_{M(\mathbb{T})} \leq a_{0}$

$$
\forall f \in C(\mathbb{T}), \quad \Psi(f)=\int_{\mathbb{T}} f(t) d \mu(t)
$$

- Taking $f(t)=e^{\text {int }}$ gives

$$
\hat{\mu}(n)=\int_{\mathbb{T}} e^{i n t} d \mu(t)=\Psi\left(e^{i n t}\right)=a_{n}
$$

- Furthermore $\mu$ is a positive measure because if $f \geq 0$

$$
\int_{\mathbb{T}} f(t) d \mu(t)=\Psi(f)=\lim _{n \rightarrow+\infty} \Psi\left(P_{n}\right)=\lim _{n, k \rightarrow+\infty} \Psi_{k}\left(P_{n}\right) \geq 0
$$

## Translation invariant kernels on $\mathbb{R}^{d}$

## Definition

A kernel $K: \mathbb{R}^{d} \times \mathbb{R}^{d} \mapsto \mathbb{R}$ is called translation invariant (t.i.), or shift-invariant, if it only depends on the difference between its argument, i.e.:

$$
\forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^{d}, \quad K(\mathbf{x}, \mathbf{y})=\varphi(\mathbf{x}-\mathbf{y})
$$

for some function $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$. Such a function $\varphi$ is called positive definite if the corresponding kernel $K$ is p.d.

## Translation invariant kernels on $\mathbb{R}^{d}$

## Definition

A kernel $K: \mathbb{R}^{d} \times \mathbb{R}^{d} \mapsto \mathbb{R}$ is called translation invariant (t.i.), or shift-invariant, if it only depends on the difference between its argument, i.e.:

$$
\forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^{d}, \quad K(\mathbf{x}, \mathbf{y})=\varphi(\mathbf{x}-\mathbf{y})
$$

for some function $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$. Such a function $\varphi$ is called positive definite if the corresponding kernel $K$ is p.d.

## Theorem (Bochner)

A continuous function $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is p.d. if and only if it is the Fourier-Stieltjes transform of a symmetric and positive finite Borel measure $\mu \in M\left(\mathbb{R}^{d}\right)$

## Fourier-Stieltjes transform on $\mathbb{R}^{d}$

- $C_{0}\left(\mathbb{R}^{d}\right)$ the set of continuous functions on $\mathbb{R}^{d}$ that vanish at infinity
- $M\left(\mathbb{R}^{d}\right)$ the finite complex Borel measures on $\mathbb{R}^{d}$
- $M\left(\mathbb{R}^{d}\right)$ can be identified as the dual space $\left(C_{0}\left(\mathbb{R}^{d}\right)\right)^{*}$ : for any continuous/bounded linear functional $\psi: C_{0}\left(\mathbb{R}^{d}\right) \rightarrow \mathbb{C}$ there exists $\mu \in M\left(\mathbb{R}^{d}\right)$ such that $\psi(f)=\int_{\mathbb{R}^{d}} f(t) \overline{d \mu(t)}$ (Riesz theorem).

## Definition (Fourier-Stieltjes transform)

For any $\mu \in M\left(\mathbb{R}^{d}\right)$, the Fourier-Stieltjes transform of $\mu$ is the function:

$$
\forall \boldsymbol{\omega} \in \mathbb{R}^{d}, \quad \hat{\mu}(\boldsymbol{\omega})=\int_{\mathbb{R}^{d}} e^{-i \boldsymbol{\omega}^{\top} \mathbf{x}} d \mu(\mathbf{x})
$$

## Fourier-Stieltjes transform on $\mathbb{R}^{d}$

- This extends the standard Fourier transform for integrable functions by taking $d \mu(\mathbf{x})=f(\mathbf{x}) d \mathbf{x}$.
- For $\mu \in M\left(\mathbb{R}^{d}\right), \hat{\mu}$ is still uniformly continuous, but $\hat{\mu}(\boldsymbol{\omega})$ does not necessarily go to 0 at infinity (e.g., take the Dirac $\mu=\delta_{0}$, then $\hat{\mu}(\boldsymbol{\omega})=1$ for all $\boldsymbol{\omega}$ )
- Parseval's formula: if $\mu \in M\left(\mathbb{R}^{d}\right)$, and both $g, \hat{g}$ are in $L^{1}\left(\mathbb{R}^{d}\right)$, then

$$
\int_{\mathbb{R}^{d}} g(\mathbf{x}) d \mu(\mathbf{x})=\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \hat{g}(\boldsymbol{\omega}) \hat{\mu}(-\boldsymbol{\omega}) d \boldsymbol{\omega} .
$$

In particular, if $g \in L^{1}\left(\mathbb{R}^{d}\right) \cap L^{2}\left(\mathbb{R}^{d}\right)$,

$$
\int_{\mathbb{R}^{d}} g(\mathbf{x})^{2} d \mathbf{x}=\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \hat{g}(\boldsymbol{\omega})^{2} d \boldsymbol{\omega}
$$

## Proof of Bochner's theorem: $\Leftarrow$

If $\varphi=\hat{\mu}$ for some $\mu \in M(\mathbb{T})$ positive, then for any $n \in \mathbb{N}$, $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n} \in \mathbb{R}^{d}$ and $z_{1}, \ldots, z_{n} \in \mathbb{R}$ (or $\mathbb{C}$ ):

$$
\begin{aligned}
\sum_{i=1}^{n} \sum_{j=1}^{n} z_{i} \bar{z}_{j} \varphi\left(\mathbf{x}_{i}-\mathbf{x}_{j}\right) & =\sum_{i=1}^{n} \sum_{j=1}^{n} z_{i} \bar{z}_{j} \int_{\mathbb{R}^{d}} e^{-i\left(\mathbf{x}_{i}-\mathbf{x}_{j}\right)^{\top} \mathbf{t}} d \mu(\mathbf{t}) \\
& =\sum_{i=1}^{n} \sum_{j=1}^{n} z_{i} \bar{z}_{j} \int_{\mathbb{R}^{d}} e^{-i \mathbf{x}_{i}^{\top} \mathbf{t}} e^{i \mathbf{x}_{j}^{\top} \mathbf{t}} d \mu(\mathbf{t}) \\
& =\int_{\mathbb{R}^{d}}\left|\sum_{j=1}^{n} z_{j} e^{-i \mathbf{x}_{j}^{\top} \mathbf{t}}\right|^{2} d \mu(\mathbf{t}) \\
& \geq 0
\end{aligned}
$$

If $\mu$ is symmetric then, in addition, $\varphi$ is real-valued.

## Proof of Bochner's theorem: $\Rightarrow(1 / 5)$

## Lemma

Let $\varphi: \mathbb{R} \rightarrow \mathbb{R}$ continuous. If there exists $C \geq 0$ such that

$$
\left|\frac{1}{2 \pi} \int_{\mathbb{R}} \hat{g}(\xi) \varphi(-\xi) d \xi\right| \leq C \sup _{x \in \mathbb{R}}|g(x)|
$$

for every continuous function $g \in L^{1}(\mathbb{R})$ such that $\hat{g}$ is continuous and has compact support, then $\varphi$ is the Fourier-Stieljes transform of a measure $\mu \in M(\mathbb{R})$.

Proof: Let $\mathcal{G} \subset C_{0}(\mathbb{R})$ be the set of functions $g \in L^{1}(\mathbb{R})$ such that $\hat{g}$ is continuous and has compact support. $\Psi: g \mapsto \frac{1}{2 \pi} \int_{\mathbb{R}} \hat{g}(\xi) \varphi(-\xi) d \xi$ is linear and continuous on $\mathcal{G}$, and can be extended to $C_{0}(\mathbb{R})$ by density of $\mathcal{G}$. By Riesz theorem, there exists $\mu \in M(\mathbb{R})$ such that $\psi(g)=\int_{\mathbb{R}} g(x) d \mu(x)=\frac{1}{2 \pi} \int_{\mathbb{R}} \hat{g}(\xi) \hat{\mu}(-\xi) d \xi$, using Parceval's formula for the second equality. This must hold for all $g$, so $\varphi=\hat{\mu}$. Note: the converse is also true.

## Proof of Bochner's theorem: $\Rightarrow(2 / 5)$

- We consider $d=1$. Generalization to $d>1$ is trivial.
- Let $\varphi: \mathbb{R} \rightarrow \mathbb{R}$ continuous and p.d.
- For any $\lambda>0$, the sequence $\{\varphi(n \lambda)\}_{n \in \mathbb{Z}}$ is p.d., so by Herglotz's theorem there exists a positive measure $\mu_{\lambda} \in M(\mathbb{T})$ such that

$$
\varphi(\lambda n)=\hat{\mu}_{\lambda}(n),
$$

and $\left\|\mu_{\lambda}\right\|_{M(\mathbb{T})}=\hat{\mu}_{\lambda}(0)=\varphi(0)$.

- Let $g \in L^{1}(\mathbb{R})$ continuous such that $\hat{g}$ is continuous and has compact support.
- For any $\epsilon>0$ there exists $\lambda>0$ such that

$$
\left|\frac{1}{2 \pi} \int_{\mathbb{R}} \hat{g}(\xi) \varphi(-\xi) d \xi\right|<\left|\frac{\lambda}{2 \pi} \sum_{n \in \mathbb{Z}} \hat{g}(\lambda n) \varphi(-\lambda n)\right|+\epsilon
$$

by approximating the integral by its Riemann sums (where the width of each rectangle is $\lambda$ ).

## Proof of Bochner's theorem: $\Rightarrow(3 / 5)$

- For $t \in \mathbb{T}$ let:

$$
G_{\lambda}(t)=\sum_{m \in \mathbb{Z}} g\left(\frac{t+2 \pi m}{\lambda}\right)
$$

- Given the regularity and decay of $g$, we can find a sufficiently small $\lambda$ to ensure

$$
\sup _{t \in \mathbb{T}}\left|G_{\lambda}(t)\right| \leq \sup _{x \in \mathbb{R}}|g(x)|+\epsilon
$$

## Proof of Bochner's theorem: $\Rightarrow(3 / 5)$

- In addition, for any $n \in \mathbb{Z}$ :

$$
\begin{aligned}
\hat{G}_{\lambda}(n) & =\frac{1}{2 \pi} \int_{\mathbb{T}} e^{-i n t} G_{\lambda}(t) d t \\
& =\frac{1}{2 \pi} \sum_{m \in \mathbb{Z}} \int_{0}^{2 \pi} e^{-i n t} g\left(\frac{t+2 \pi m}{\lambda}\right) d t \\
& =\frac{\lambda}{2 \pi} \sum_{m \in \mathbb{Z}} \int_{\frac{2 \pi m}{\lambda}}^{\frac{2 \pi(m+1)}{\lambda}} e^{-i n(\lambda u+2 \pi m)} g(u) d u \\
& =\frac{\lambda}{2 \pi} \sum_{m \in \mathbb{Z}} \int_{\frac{2 \pi m}{\lambda}}^{\frac{2 \pi(m+1)}{\lambda}} e^{-i n \lambda u} g(u) d u \\
& =\frac{\lambda}{2 \pi} \int_{\mathbb{R}} e^{-i n \lambda u} g(u) d u \\
& =\frac{\lambda}{2 \pi} \hat{g}(\lambda n)
\end{aligned}
$$

## Proof of Bochner's theorem: $\Rightarrow(4 / 5)$

- This gives:

$$
\begin{aligned}
\left|\frac{\lambda}{2 \pi} \sum_{n \in \mathbb{Z}} \hat{g}(\lambda n) \varphi(-\lambda n)\right| & =\left|\sum_{n \in \mathbb{Z}} \hat{G}_{\lambda}(n) \overline{\hat{\mu}_{\lambda}(-n)}\right| \\
& =\left|\frac{1}{2 \pi} \int_{\mathbb{T}} G_{\lambda}(t) \overline{d \mu_{\lambda}(t)}\right| \quad \quad \text { (Parceval) } \\
& \leq\left\|\mu_{\lambda}\right\|_{M(\mathbb{T})} \sup _{t \in \mathbb{T}}\left|G_{\lambda}(t)\right| \\
& \leq C \sup _{t \in \mathbb{T}}\left|G_{\lambda}(t)\right| \\
& \leq C \sup _{x \in \mathbb{R}}|g(x)|+C \epsilon
\end{aligned}
$$

with $C=\varphi(0)$.

## Proof of Bochner's theorem: $\Rightarrow(5 / 5)$

- Putting it all together gives:

$$
\left|\frac{1}{2 \pi} \int_{\mathbb{R}} \hat{g}(\xi) \varphi(-\xi) d \xi\right|<C \sup _{x \in \mathbb{R}}|g(x)|+(C+1) \epsilon
$$

- This is true for all $\epsilon>0$ which implies

$$
\left|\frac{1}{2 \pi} \int_{\mathbb{R}} \hat{g}(\xi) \varphi(-\xi) d \xi\right| \leq C \sup _{x \in \mathbb{R}}|g(x)|
$$

- We conclude from the lemma that $\varphi=\hat{\mu}$ for some $\mu \in M(\mathbb{R})$, which satisfies

$$
\frac{1}{2 \pi} \int_{\mathbb{R}} \hat{g}(\xi) \varphi(-\xi) d \xi=\int_{\mathbb{R}} g(x) d \mu(x)
$$

- When $g \geq 0$, this is approximated by $\frac{1}{2 \pi} \int_{\mathbb{T}} G_{\lambda}(t) \overline{d \mu_{\lambda}(t)}$ for small $\lambda$, which is $\geq 0$ because $\mu_{\lambda}$ is a positive measure and $G_{\lambda} \geq 0$ like $g$. Consequently, $\mu$ is a positive measure.

## RKHS of translation invariant kernels

## Theorem

Let $K(\mathbf{x}, \mathbf{t})=\varphi(\mathbf{x}-\mathbf{t})$ be a translation invariant p.d. kernel, such that $\varphi$ is integrable on $\mathbb{R}^{d}$ as well as its Fourier transform $\hat{\varphi}$. The subset $\mathcal{H}$ of $L_{2}\left(\mathbb{R}^{d}\right)$ that consists of integrable and continuous functions $f$ such that:

$$
\|f\|_{\mathcal{H}_{\mathcal{H}}}^{2}:=\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \frac{|\hat{f}(\boldsymbol{\omega})|^{2}}{\hat{\varphi}(\boldsymbol{\omega})} d \omega<+\infty
$$

endowed with the inner product:

$$
\langle f, g\rangle_{\mathcal{H}}:=\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \frac{\hat{f}(\omega) \overline{\hat{g}(\omega)}}{\hat{\varphi}(\omega)} d \omega
$$

is a RKHS with $K$ as r.k.

## Proof

- $\mathcal{H}$ is a Hilbert space: exercise.
- For $\mathbf{x} \in \mathbb{R}^{d}, K_{\mathbf{x}}(\mathbf{y})=K(\mathbf{x}, \mathbf{y})=\varphi(\mathbf{x}-\mathbf{y})$ therefore:

$$
\hat{K}_{\mathbf{x}}(\boldsymbol{\omega})=\int e^{-i \boldsymbol{\omega}^{\top} \mathbf{u}} \varphi(\mathbf{u}-\mathbf{x}) d \mathbf{u}=e^{-i \boldsymbol{\omega}^{\top} \mathbf{x}} \hat{\varphi}(\boldsymbol{\omega})
$$

- This leads to $K_{\mathrm{x}} \in \mathcal{H}$, because:

$$
\int_{\mathbb{R}^{d}} \frac{\left|\hat{K}_{x}(\omega)\right|^{2}}{\hat{\varphi}(\omega)} \leq \int_{\mathbb{R}^{d}}|\hat{\varphi}(\omega)|<\infty
$$

- Moreover, if $f \in \mathcal{H}$ and $\mathbf{x} \in \mathbb{R}^{d}$, we have:

$$
\begin{aligned}
\left\langle f, K_{\mathrm{x}}\right\rangle_{\mathcal{H}} & =\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \frac{\hat{K}_{\mathrm{x}}(\omega) \overline{\hat{f}(\omega)}}{\hat{\varphi}(\boldsymbol{\omega})} d \omega=\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \overline{\hat{f}(\omega)} e^{-i \omega^{\top} \mathrm{x}} d \omega \\
& =f(\mathrm{x})
\end{aligned}
$$

## Example

## Gaussian kernel

$$
K(x, y)=e^{-\frac{(x-y)^{2}}{2 \sigma^{2}}}
$$

corresponds to:

$$
\begin{aligned}
\varphi(t) & =e^{-\frac{t^{2}}{2 \sigma^{2}}} \\
\hat{\varphi}(\omega) & =e^{-\frac{\sigma^{2} \omega^{2}}{2}}
\end{aligned}
$$

and

$$
\mathcal{H}=\left\{f: \int|\hat{f}(\omega)|^{2} e^{\frac{\sigma^{2} \omega^{2}}{2}} d \omega<\infty\right\} .
$$

In particular, all functions in $\mathcal{H}$ are infinitely differentiable with all derivatives in $L^{2}$.

## Example

## Laplace kernel

$$
K(x, y)=\frac{1}{2} e^{-\gamma|x-y|}
$$

corresponds to:

$$
\begin{aligned}
& \varphi(t o)=\frac{1}{2} e^{-\gamma|t|} \\
& \hat{\varphi}(\omega)=\frac{\gamma}{\gamma^{2}+\omega^{2}}
\end{aligned}
$$

and

$$
\mathcal{H}=\left\{f: \int|\hat{f}(\omega)|^{2} \frac{\left(\gamma^{2}+\omega^{2}\right)}{\gamma} d \omega<\infty\right\}
$$

the set of functions $L^{2}$ differentiable with derivatives in $L^{2}$ (Sobolev norm).

## Example

## Low-frequency filter

$$
K(x, y)=\frac{\sin (\Omega(x-y))}{\pi(x-y)}
$$

corresponds to:

$$
\begin{aligned}
\varphi(t) & =\frac{\sin (\Omega t)}{\pi t} \\
\hat{\varphi}(\omega) & =1_{[-\Omega, \Omega]}(\omega)
\end{aligned}
$$

and

$$
\mathcal{H}=\left\{f: \int_{|\omega|>\Omega}|\hat{f}(\omega)|^{2} d \omega=0\right\}
$$

the set of functions whose spectrum is included in $[-\Omega, \Omega]$.

## Recap on Green, Mercer, Bochner families

Up to specific assumptions for each of the following kernel families,

|  | Kernel | RKHS H |
| :--- | :--- | :---: |
| Green | Green func. of $D^{*} D$ | $L_{2}(\mathcal{X})$ with $\langle D f, D g\rangle_{L_{2}(\mathcal{X})}$ |
| Mercer | $\sum_{k=1}^{\infty} \lambda_{k} \psi_{k}(x) \psi_{k}(y)$ | $\left\{f=\sum_{k=1}^{\infty} a_{k} \psi_{k}: \sum_{k=1}^{\infty} \frac{a_{k}^{2}}{\lambda_{k}}<+\infty\right\}$ |
| Fourier | $\kappa(x-y)$ <br> $\int \hat{\kappa}(\omega) e^{i \omega(x-y)} d \omega$ | $\left\{\begin{array}{c}f \in \underbrace{L_{2}\left(\mathbb{R}^{d}\right)}_{\begin{array}{l}\text { +continuous } \\ \text { +integrable }\end{array}}: \int \frac{\|\hat{f}(\omega)\|^{2}}{\hat{\kappa}(\omega)} d \omega<+\infty\end{array}\right\}$ |

## Recap on Green, Mercer, Bochner families

Up to specific assumptions for each of the following kernel families,

|  | Kernel | Squared Norm $\\|\cdot\\|_{\mathcal{H}}^{2}$ |
| :--- | :--- | :---: |
| Green | Green func. of $D^{*} D$ | $\\|D f\\|_{L_{2}(\mathcal{X})}^{2}$ |
| Mercer | $\sum_{k=1}^{\infty} \lambda_{k} \psi_{k}(x) \psi_{k}(y)$ | $\sum_{k=1}^{\infty} \frac{a_{k}^{2}}{\lambda_{k}}$ for $f=\sum_{k=1}^{\infty} a_{k} \psi_{k}$ |
| Fourier | $\kappa(x-y)$ | $\frac{1}{(2 \pi)^{d}} \int \frac{\|\hat{f}(\omega)\|^{2}}{\hat{\kappa}(\omega)} d \omega$ |

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Green kernels
- Mercer kernels
- Convergence rates of KRR for Mercer kernels
- Shift-invariant kernels
- Generalization to semigroups
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Generalization to semigroups (cf Berg et al., 1983)

## Definition

- A semigroup $(S, \circ)$ is a nonempty set $S$ equipped with an associative composition $\circ$ and a neutral element $e$.
- A semigroup with involution $(S, \circ, *)$ is a semigroup $(S, \circ)$ together with a mapping $*: S \rightarrow S$ called involution satisfying:
(1) $(s \circ t)^{*}=t^{*} \circ s^{*}$, for $s, t \in S$.
(2) $\left(s^{*}\right)^{*}=s$ for $s \in S$.

## Examples

- Any group ( $G, \circ$ ) is a semigroup with involution when we define $s^{*}=s^{-1}$.
- Any abelian semigroup $(S,+)$ is a semigroup with involution when we define $s^{*}=s$, the identical involution.

## Positive definite functions on semigroups

## Definition

Let $(S, \circ, *)$ be a semigroup with involution. A function $\varphi: S \rightarrow \mathbb{R}$ is called positive definite if the function:

$$
\forall s, t \in S, \quad K(s, t)=\varphi\left(s^{*} \circ t\right)
$$

is a p.d. kernel on $S$.

## Example: translation invariant kernels

$\left(\mathbb{R}^{d},+,-\right)$ is an abelian group with involution. A function $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is p.d. if the function

$$
K(\mathbf{x}, \mathbf{y})=\varphi(\mathbf{x}-\mathbf{y})
$$

is p.d. on $\mathbb{R}^{d}$ (translation invariant kernels).

## Semicharacters

## Definition

A function $\rho: S \rightarrow \mathbb{C}$ on an abelian semigroup with involution $(S,+, *)$ is called a semicharacter if
(1) $\rho(0)=1$,
(2) $\rho(s+t)=\rho(s) \rho(t)$ for $s, t \in S$,
(3) $\rho\left(s^{*}\right)=\overline{\rho(s)}$ for $s \in S$.

The set of semicharacters on $S$ is denoted by $S^{*}$.

## Remarks

- If $*$ is the identity, a semicharacter is automatically real-valued.
- If $(S,+)$ is an abelian group and $s^{*}=-s$, a semicharacter has its values in the circle group $\{z \in \mathbb{C}||z|=1\}$ and is a group character.

## Semicharacters are p.d.

## Lemma

Every semicharacter is p.d., in the sense that:

- $K(s, t)=\overline{K(t, s)}$,
- $\sum_{i, j=1}^{n} a_{i} \overline{a_{j}} K\left(x_{i}, x_{j}\right) \geq 0$.

## Proof

Direct from definition, e.g.,

$$
\sum_{i, j=1}^{n} a_{i} \overline{a_{j}} \rho\left(x_{i}+x_{j}^{*}\right)=\sum_{i, j=1}^{n} a_{i} \overline{a_{j}} \rho\left(x_{i}\right) \overline{\rho\left(x_{j}\right)} \geq 0
$$

## Examples

- $\varphi(t)=e^{\beta t}$ on $(\mathbb{R},+, l d)$.
- $\varphi(t)=e^{i \omega t}$ on $(\mathbb{R},+,-)$.

## Integral representation of p.d. functions

## Definition

- An function $\alpha: S \rightarrow \mathbb{R}$ on a semigroup with involution is called an absolute value if (i) $\alpha(e)=1$, (ii) $\alpha(s \circ t) \leq \alpha(s) \alpha(t)$, and (iii) $\alpha\left(s^{*}\right)=\alpha(s)$.
- A function $f: S \rightarrow \mathbb{R}$ is called exponentially bounded if there exists an absolute value $\alpha$ and a constant $C>0$ s.t. $|f(s)| \leq C \alpha(s)$ for $s \in S$.

## Theorem

Let $(S,+, *)$ an abelian semigroup with involution. A function $\varphi: S \rightarrow \mathbb{R}$ is p.d. and exponentially bounded (resp. bounded) if and only if it has a representation of the form:

$$
\varphi(s)=\int_{S^{*}} \rho(s) d \mu(\rho)
$$

where $\mu$ is a Radon measure with compact support on $S^{*}$ (resp. on $\hat{S}$, the set of bounded semicharacters).

## Proof

## Sketch (details in Berg et al., 1983, Theorem 4.2.5)

- For an absolute value $\alpha$, the set $P_{1}^{\alpha}$ of $\alpha$-bounded p.d. functions that satisfy $\varphi(0)=1$ is a compact convex set whose extreme points are precisely the $\alpha$-bounded semicharacters.
- If $\varphi$ is p.d. and exponentially bounded then there exists an absolute value $\alpha$ such that $\varphi(0)^{-1} \varphi \in P_{1}^{\alpha}$.
- By the Krein-Milman theorem there exits a Radon probability measure on $P_{1}^{\alpha}$ having $\varphi(0)^{-1} \varphi$ as barycentre.

## Remarks

- The result is not true without the assumption of exponentially boundedsemicharacters.
- In the case of abelian groups with $s^{*}=-s$ this reduces to Bochner's theorem for discrete abelian groups, cf. Rudin (1962).

## Example 1: $\left(R_{+},+, l d\right)$

## Semicharacters

- $S=\left(\mathbb{R}_{+},+\right.$, ld $)$is an abelian semigroup.
- P.d. functions are nonnegative, because $\varphi(x)=\varphi(\sqrt{x})^{2}$.
- The set of bounded semicharacters is exactly the set of functions:

$$
s \in \mathbb{R}_{+} \mapsto \rho_{a}(s)=e^{-a s}
$$

for $a \in[0,+\infty]$ (left as exercice).

- Non-bounded semicharacters are more difficult to characterize; in fact there exist nonmeasurable solutions of the equation $h(x+y)=h(x) h(y)$.

## Example 1: $\left(R_{+},+, I d\right)$ (cont.)

## P.d. functions

- By the integral representation theorem for bounded semi-characters we obtain that a function $\varphi: \mathbb{R}_{+} \rightarrow \mathbb{R}$ is p.d. and bounded if and only if it has the form:

$$
\varphi(s)=\int_{0}^{\infty} e^{-a s} d \mu(a)+b \rho_{\infty}(s)
$$

where $\mu \in \mathcal{M}_{+}^{b}\left(\mathbb{R}_{+}\right)$and $b \geq 0$.

- The first term is the Laplace transform of $\mu . \varphi$ is p.d., bounded and continuous iff it is the Laplace transform of a measure in $\mathcal{M}_{+}^{b}(\mathbb{R})$.

## Example 2: Semigroup kernels for finite measures $(1 / 6)$

## Setting

- We assume that data to be processed are "bags-of-points", i.e., sets of points (with repeats) of a space $\mathcal{U}$.
- Example : a finite-length string as a set of $k$-mers.
- How to define a p.d. kernel between any two bags that only depends on the union of the bags?
- See details and proofs in Cuturi et al. (2005).

## Example 2: Semigroup kernels for finite measures $(2 / 6)$

## Semigroup of bounded measures

- We can represent any bag-of-point $\mathbf{x}$ as a finite measure on $\mathcal{U}$ :

$$
\mathbf{x}=\sum_{i} a_{i} \delta_{x_{i}}
$$

where $a_{i}$ is the number of occurrences on $\mathbf{x}_{i}$ in the bag.

- The measure that represents the union of two bags is the sum of the measures that represent each individual bag.
- This suggests to look at the semigroup $\left(\mathcal{M}_{+}^{b}(\mathcal{U}),+, I d\right)$ of bounded Radon measures on $\mathcal{U}$ and to search for p.d. functions $\varphi$ on this semigroup.

## Example 2: Semigroup kernels for finite measures (3/6)

## Semicharacters

- For any Borel measurable function $f: \mathcal{U} \rightarrow \mathbb{R}$ the function $\rho_{f}: \mathcal{M}_{+}^{b}(\mathcal{U}) \rightarrow \mathbb{R}$ defined by:

$$
\rho_{f}(\mu)=e^{\mu[f]}
$$

is a semicharacter on $\left(\mathcal{M}_{+}^{b}(\mathcal{U}),+\right)$.

- Conversely, $\rho$ is continuous semicharacter (for the topology of weak convergence) if and only if there exists a continuous function $f: \mathcal{U} \rightarrow \mathbb{R}$ such that $\rho=\rho_{f}$.
- No such characterization for non-continuous characters, even bounded.

## Example 2: Semigroup kernels for finite measures (4/6)

## Corollary

Let $\mathcal{U}$ be a Hausdorff space. For any Radon measure $\mu \in \mathcal{M}_{+}^{c}(C(\mathcal{U}))$ with compact support on the Hausdorff space of continuous real-valued functions on $\mathcal{U}$ endowed with the topology of pointwise convergence, the following function $K$ is a continuous p.d. kernel on $\mathcal{M}_{+}^{b}(\mathcal{U})$ (endowed with the topology of weak convergence):

$$
K(\mu, \nu)=\int_{C(\mathcal{X})} e^{\mu[f]+\nu[f]} d \mu(f)
$$

## Remarks

The converse is not true: there exist continuous p.d. kernels that do not have this integral representation (it might include non-continuous semicharacters)

## Example 2: Semigroup kernels for finite measures (5/6)

## Example : entropy kernel

- Let $\mathcal{X}$ be the set of probability densities (w.r.t. some reference measure) on $\mathcal{U}$ with finite entropy:

$$
h(\mathbf{x})=-\int_{\mathcal{U}} \mathbf{x} \ln \mathbf{x} .
$$

- Then the following entropy kernel is a p.d. kernel on $\mathcal{X}$ for all $\beta>0$ :

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=e^{-\beta h\left(\frac{x+x}{2}\right)} .
$$

- Remark: only valid for densities (e.g., for a kernel density estimator from a bag-of-parts)

## Example 2: Semigroup kernels for finite measures $(6 / 6)$

## Examples: inverse generalized variance kernel

- Let $\mathcal{U}=\mathbb{R}^{d}$ and $\mathcal{M}_{+}^{V}(\mathcal{U})$ be the set of finite measure $\mu$ with second order moment and non-singular variance

$$
\Sigma(\mu)=\mu\left[x x^{\top}\right]-\mu[x] \mu[x]^{\top}
$$

- Then the following function is a p.d. kernel on $\mathcal{M}_{+}^{V}(\mathcal{U})$, called the inverse generalized variance kernel:

$$
K\left(\mu, \mu^{\prime}\right)=\frac{1}{\operatorname{det} \sum\left(\frac{\mu+\mu^{\prime}}{2}\right)} .
$$

- Generalization possible with regularization and kernel trick.

## Application of semigroup kernel

$$
\begin{aligned}
& \Sigma_{1,1}=0.0552 \\
& \Sigma_{2,2}=0.0013
\end{aligned}
$$

$\Sigma_{1,1}^{\prime}=0.0441$
$\Sigma_{2,2}^{\prime}=0.0237$

$$
\begin{aligned}
& \Sigma_{1,1}^{\prime \prime}=0.0497 \\
& \Sigma_{2,2}^{\prime \prime}=0.0139
\end{aligned}
$$

Weighted linear PCA of two different measures, with the first PC shown. Variances captured by the first and second PC are shown. The generalized variance kernel is the inverse of the product of the two values.

## Kernelization of the IGV kernel

## Motivations

- Gaussian distributions may be poor models.
- The method fails in large dimension

## Solution

(1) Regularization:

$$
K_{\lambda}\left(\mu, \mu^{\prime}\right)=\frac{1}{\operatorname{det}\left(\Sigma\left(\frac{\mu+\mu^{\prime}}{2}\right)+\lambda I_{d}\right)} .
$$

(2) Kernel trick: the non-zero eigenvalues of $U U^{\top}$ and $U^{\top} U$ are the same $\Longrightarrow$ replace the covariance matrix by the centered Gram matrix (technical details in Cuturi et al., 2005).

## Semigroup kernel remarks

## Motivations

- A very general formalism to exploit an algebraic structure of the data.
- Kernel IVG kernel has given good results for character recognition from a subsampled image.
- The main motivation is more generally to develop kernels for complex objects from which simple "patches" can be extracted.
- The extension to nonabelian groups (e.g., permutation in the symmetric group) might find natural applications.

## Kernel examples: Summary

- Many notions of smoothness can be translated as RKHS norms for particular kernels (eigenvalues convolution operator, Sobolev norms and Green operators, Fourier transforms...).
- There is no "uniformly best kernel", but rather a large toolbox of methods and tricks to encode prior knowledge and exploit the nature or structure of the data.
- In the following sections we focus on particular data and applications to illustrate the process of kernel design.

(6) Open Problems and Research Topics

## Motivation

Kernel methods are sometimes criticized for their lack of flexibility: a large effort is spent in designing by hand the kernel.

Question
How do we design a kernel adapted to the data?

## Motivation

Kernel methods are sometimes criticized for their lack of flexibility: a large effort is spent in designing by hand the kernel.

Question
How do we design a kernel adapted to the data?
Answer
A successful strategy is given by kernels for generative models, which are/have been the state of the art in many fields, including representation of image and sequence data representation.

## Parametric model

A model is a family of distributions

$$
\left\{P_{\theta}, \theta \in \Theta \subset \mathbb{R}^{m}\right\} \subseteq \mathcal{M}_{1}^{+}(\mathcal{X})
$$

## Outline

(4) The Kernel Jungle

- Kernels for probabilistic models - Fisher kernel
- Mutual information kernels
- Marginalized kernels
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Fisher kernel

## Definition

- Fix a parameter $\theta_{0} \in \Theta$ (obtained for instance by maximum likelihood over a training set).
- For each sequence $\mathbf{x}$, compute the Fisher score vector:

$$
\Phi_{\theta_{0}}(\mathbf{x})=\left.\nabla_{\theta} \log P_{\theta}(\mathbf{x})\right|_{\theta=\theta_{0}},
$$

which can be interpreted as the local contribution of each parameter.

- Form the kernel (Jaakkola et al., 2000):

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\Phi_{\theta_{0}}(\mathbf{x})^{\top} \mathbf{I}\left(\theta_{0}\right)^{-1} \Phi_{\theta_{0}}\left(\mathbf{x}^{\prime}\right),
$$

where $\mathbf{I}\left(\theta_{0}\right)=\mathbb{E}\left[\Phi_{\theta_{0}}(\mathbf{x}) \Phi_{\theta_{0}}(\mathbf{x})^{\top}\right]$ is the Fisher information matrix.
Note: when $\theta_{0}$ is the ML estimator, $\mathbb{E}\left[\Phi_{\theta_{0}}(\mathbf{x})\right]=0$ and $\mathbf{I}\left(\theta_{0}\right)$ is a covariance matrix.

## Fisher kernel properties (1/2)

- The Fisher score describes how each parameter contributes to the process of generating a particular example
- A kernel classifier employing the Fisher kernel derived from a model that contains the label as a latent variable is, asymptotically, at least as good as the MAP labelling based on the model (Jaakkola and Haussler, 1999).
- A variant of the Fisher kernel (called the Tangent of Posterior kernel) can also improve over the direct posterior classification by helping to correct the effect of estimation errors in the parameter (Tsuda et al., 2002).

## Fisher kernel properties (2/2)

## Lemma

The Fisher kernel is invariant under change of parametrization.

- Consider indeed a different parametrization given by some diffeomorphism $\lambda=f(\theta)$. The Jacobian matrix relating the parametrization is denoted by $[\mathbf{J}]_{i j}=\frac{\partial \theta_{j}}{\partial \lambda_{i}}$.
- The gradient of log-likelihood w.r.t. to the new parameters is

$$
\Phi_{\lambda_{0}}(\mathbf{x})=\nabla_{\lambda} \log P_{\lambda_{0}}(\mathbf{x})=\mathbf{J} \nabla_{\theta} \log P_{\theta_{0}}(\mathbf{x})=\mathbf{J} \Phi_{\theta_{0}}(\mathbf{x})
$$

- The Fisher information matrix is

$$
\mathbf{I}\left(\lambda_{0}\right)=\mathbb{E}\left[\Phi_{\lambda_{0}}(\mathbf{x}) \Phi_{\lambda_{0}}(\mathbf{x})^{\top}\right]=\mathbf{J} \mathbf{l}\left(\theta_{0}\right) \mathbf{J}^{\top}
$$

- We conclude by noticing that $\mathbf{I}\left(\lambda_{0}\right)^{-1}=\mathbf{J}^{-1} \mathbf{I}\left(\theta_{0}\right)^{-1} \mathbf{J}^{\top-1}$ :

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\Phi_{\theta_{0}}(\mathbf{x})^{\top} \mathbf{l}\left(\theta_{0}\right)^{-1} \Phi_{\theta_{0}}\left(\mathbf{x}^{\prime}\right)=\Phi_{\lambda_{0}}(\mathbf{x})^{\top} \mathbf{l}\left(\lambda_{0}\right)^{-1} \Phi_{\lambda_{0}}\left(\mathbf{x}^{\prime}\right)
$$

## Fisher kernel in practice

- $\Phi_{\theta_{0}}(\mathbf{x})$ can be computed explicitly for many models (e.g., HMMs), where the model is first estimated from data.
- $\mathbf{I}\left(\theta_{0}\right)$ is often replaced by the identity matrix for simplicity.
- Several different models (i.e., different $\theta_{0}$ ) can be trained and combined.
- The Fisher vectors are defined as $\varphi_{\theta_{0}}(\mathbf{x})=\mathbf{I}\left(\theta_{0}\right)^{-1 / 2} \Phi_{\theta_{0}}(\mathbf{x})$. They are explicitly computed and correspond to an explicit embedding: $K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\varphi_{\theta_{0}}(\mathbf{x})^{\top} \varphi_{\theta_{0}}\left(\mathbf{x}^{\prime}\right)$.

## Fisher kernels: example with Gaussian data model $(1 / 2)$

Consider a normal distribution $\mathcal{N}\left(\mu, \sigma^{2}\right)$ and denote by $\alpha=1 / \sigma^{2}$ the inverse variance, i.e., precision parameter. With $\theta=(\mu, \alpha)$, we have

$$
\log P_{\theta}(x)=\frac{1}{2} \log \alpha-\frac{1}{2} \log (2 \pi)-\frac{1}{2} \alpha(x-\mu)^{2},
$$

and thus

$$
\frac{\partial \log P_{\theta}(x)}{\partial \mu}=\alpha(x-\mu), \quad \frac{\partial \log P_{\theta}(x)}{\partial \alpha}=\frac{1}{2}\left[\frac{1}{\alpha}-(x-\mu)^{2}\right]
$$

and (exercise)

$$
\mathbf{I}(\theta)=\left(\begin{array}{cc}
\alpha & 0 \\
0 & (1 / 2) \alpha^{-2}
\end{array}\right)
$$

The Fisher vector is then

$$
\varphi_{\theta}(x)=\binom{(x-\mu) / \sigma}{(1 / \sqrt{2})\left(1-(x-\mu)^{2} / \sigma^{2}\right)}
$$

## Fisher kernels: example with Gaussian data model $(2 / 2)$

Now consider an i.i.d. data model over a set of data points $x_{1}, \ldots, x_{n}$ all distributed according to $\mathcal{N}\left(\mu, \sigma^{2}\right)$ :

$$
P_{\theta}\left(x_{1}, \ldots, x_{n}\right)=\prod_{i=1}^{n} P_{\theta}\left(x_{i}\right)
$$

Then, the Fisher vector is given by the sum of Fisher vectors of the points.

- Encodes the discrepancy in the first and second order moment of the data w.r.t. those of the model.

$$
\varphi\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n} \varphi\left(x_{i}\right)=n\binom{(\hat{\mu}-\mu) / \sigma}{\left(\sigma^{2}-\hat{\sigma}^{2}\right) /\left(\sqrt{2} \sigma^{2}\right)},
$$

- where

$$
\hat{\mu}=\frac{1}{n} \sum_{i=1}^{n} x_{i} \quad \text { and } \quad \hat{\sigma}=\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-\hat{\mu}\right)^{2} .
$$

## Application: Aggregation of visual words $(1 / 5)$

- Patch extraction and description stage:

In various contexts, images may be described as a set of patches $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ computed at interest points. For example, SIFT, HOG, LBP, color histograms, convolutional features...

- Coding stage: The set of patches is then encoded into a single representation $\varphi\left(\mathbf{x}_{i}\right)$, typically in a high-dimensional space.
- Pooling stage: For example, sum pooling

$$
\varphi\left(\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right)=\sum_{i=1}^{n} \varphi\left(\mathbf{x}_{i}\right)
$$

Fisher vectors with a Gaussian Mixture Model (GMM) is a simple and effective aggregation technique (Perronnin and Dance, 2007).

## Application: Aggregation of visual words (2/5)

Let $\theta=\left(\pi_{j}, \boldsymbol{\mu}_{j}, \boldsymbol{\Sigma}_{j}\right)_{j=1 \ldots, k}$ be the parameters of a GMM with $k$ Gaussian components. Then, the probabilistic model is given by

$$
P_{\theta}(\mathbf{x})=\sum_{j=1}^{k} \pi_{j} \mathcal{N}\left(\mathbf{x} ; \boldsymbol{\mu}_{j}, \boldsymbol{\Sigma}_{j}\right)
$$

## Remarks

- Each mixture component corresponds to a visual word, with a mean, variance, and mixing weight.
- Diagonal covariances $\boldsymbol{\Sigma}_{j}=\operatorname{diag}\left(\sigma_{j 1}, \ldots, \sigma_{j p}\right)=\operatorname{diag}\left(\boldsymbol{\sigma}_{j}\right)$ are often used for simplicity.
- This is a richer model than the traditional "bag of words" approach.
- The probabilistic model is learned offline beforehand.

## Application: Aggregation of visual words (3/5)

After cumbersome calculations (exercise), we obtain $\varphi_{\theta}\left(\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right)=$ $\left[\varphi_{\pi_{1}}(\mathbf{X}), \ldots, \varphi_{\pi_{\rho}}(\mathbf{X}), \varphi_{\boldsymbol{\mu}_{1}}(\mathbf{X})^{\top}, \ldots, \varphi_{\boldsymbol{\mu}_{\rho}}(\mathbf{X})^{\top}, \varphi_{\sigma_{1}}(\mathbf{X})^{\top}, \ldots, \varphi_{\sigma_{\rho}}(\mathbf{X})^{\top}\right]^{\top}$, with

$$
\begin{aligned}
\varphi_{\boldsymbol{\mu}_{j}}(\mathbf{X}) & =\frac{1}{n \sqrt{\pi_{j}}} \sum_{i=1}^{n} \gamma_{i j}\left(\mathbf{x}_{i}-\boldsymbol{\mu}_{j}\right) / \boldsymbol{\sigma}_{j} \\
\varphi_{\sigma_{j}}(\mathbf{X}) & =\frac{1}{n \sqrt{2 \pi_{j}}} \sum_{i=1}^{n} \gamma_{i j}\left[\left(\mathbf{x}_{i}-\boldsymbol{\mu}_{j}\right)^{2} / \boldsymbol{\sigma}_{j}^{2}-1\right]
\end{aligned}
$$

where, with an abuse of notation, the division between two vectors is meant elementwise and the scalars $\gamma_{i j}$ can be interpreted as the soft-assignment of word $i$ to component $j$ :

$$
\gamma_{i j}=\frac{\pi_{j} \mathcal{N}\left(\mathbf{x}_{i} ; \boldsymbol{\mu}_{j}, \boldsymbol{\sigma}_{j}\right)}{\sum_{l=1}^{k} \pi_{l} \mathcal{N}\left(\mathbf{x}_{i} ; \boldsymbol{\mu}_{l}, \boldsymbol{\sigma}_{l}\right)} .
$$

## Application: Aggregation of visual words (4/5)

Finally, we also have the following interpretation of encoding first and second-order statistics:

$$
\begin{aligned}
\varphi_{\boldsymbol{\mu}_{j}}(\mathbf{X}) & =\frac{\gamma_{j}}{\sqrt{\pi_{j}}}\left(\hat{\boldsymbol{\mu}}_{j}-\boldsymbol{\mu}_{j}\right) / \boldsymbol{\sigma}_{j} \\
\varphi_{\sigma_{j}}(\mathbf{X}) & =\frac{\gamma_{j}}{\sqrt{2 \pi_{j}}}\left(\hat{\sigma}_{j}^{2}-\boldsymbol{\sigma}_{j}^{2}\right) / \boldsymbol{\sigma}_{j}^{2}
\end{aligned}
$$

with
$\gamma_{j}=\sum_{i=1}^{n} \gamma_{i j} \quad$ and $\quad \hat{\boldsymbol{\mu}}_{j}=\frac{1}{\gamma_{j}} \sum_{i=1}^{n} \gamma_{i j} \mathbf{x}_{i} \quad$ and $\quad \hat{\boldsymbol{\sigma}}_{j}=\frac{1}{\gamma_{j}} \sum_{i=1}^{n} \gamma_{i j}\left(\mathbf{x}_{i}-\boldsymbol{\mu}_{j}\right)^{2}$.
The component $\varphi_{\pi}(\mathbf{X})$ is often dropped due to its negligible contribution in practice, and the resulting representation is of dimension $2 k p$ where $p$ is the dimension of the $\mathbf{x}_{i}$ 's.

## Application: Aggregation of visual words (5/5)

- FVs were state-of-the-art image representations before the revival of convolutional neural networks in 2012.

## Application: Aggregation of visual words (5/5)

- FVs were state-of-the-art image representations before the revival of convolutional neural networks in 2012.
- This is an unsupervised image representation of high dimension. They remain competitive among unsupervised methods, see the following table from Bojanowski and Joulin, 2017.

| Method | Acc@ 1 |
| :--- | ---: |
| Random (Noroozi \& Favaro, 2016) | 12.0 |
| SIFT+FV (Sánchez et al., 2013) | 55.6 |
| Wang \& Gupta (2015) | 29.8 |
| Doersch et al. (2015) | 30.4 |
| Zhang et al. (2016) $^{1}$ Noroozi \& Favaro (2016) | 35.2 |
| BiGAN (Donahue et al., 2016) | 38.1 |
| NAT | 32.2 |

Table 3. Comparison of the proposed approach to state-of-the-art unsupervised feature learning on ImageNet. A full multi-layer perceptron is retrained on top of the features. We compare to several self-supervised approaches and an unsupervised approach, i.e., BiGAN (Donahue et al., 2016). ${ }^{1}$ Noroozi \& Favaro (2016)

## Relation to classification with generative models $(1 / 3)$

Assume that we have a generative probabilistic model $P_{\theta}$ to model random variables $(X, Y)$ where $Y$ is a label in $\{1, \ldots, p\}$.

Assume that the marginals $P_{\theta}(Y=k)=\pi_{k}$ are among the model parameters $\theta$, which we can also parametrize as

$$
P_{\theta}(Y=k)=\pi_{k}=\frac{e^{\alpha_{k}}}{\sum_{k^{\prime}=1}^{p} e^{\alpha_{k^{\prime}}}}
$$

The classification of a new point $x$ can be obtained via Bayes' rule:

$$
\hat{y}(x)=\underset{k=1, \ldots, p}{\operatorname{argmax}} P_{\theta}(Y=k \mid x),
$$

where $P_{\theta}(Y=k \mid x)$ is short for $P_{\theta}(Y=k \mid X=x)$ and

$$
\begin{aligned}
P_{\theta}(Y=k \mid x) & =P_{\theta}(x \mid Y=k) P_{\theta}(Y=k) / P_{\theta}(x) \\
& =P_{\theta}(x \mid Y=k) \pi_{k} / \sum_{k^{\prime}=1}^{p} P_{\theta}\left(x \mid Y=k^{\prime}\right) \pi_{k^{\prime}}
\end{aligned}
$$

## Relation to classification with generative models $(2 / 3)$

Then, consider the Fisher score

$$
\begin{aligned}
\nabla_{\theta} \log P_{\theta}(x) & =\frac{1}{P_{\theta}(x)} \nabla_{\theta} P_{\theta}(x) \\
& =\frac{1}{P_{\theta}(x)} \nabla_{\theta} \sum_{k=1}^{p} P_{\theta}(x, Y=k) \\
& =\frac{1}{P_{\theta}(x)} \sum_{k=1}^{p} P_{\theta}(x, Y=k) \nabla_{\theta} \log P_{\theta}(x, Y=k) \\
& =\sum_{k=1}^{p} P_{\theta}(Y=k \mid x)\left[\nabla_{\theta} \log \pi_{k}+\nabla_{\theta} \log P_{\theta}(x \mid Y=k)\right]
\end{aligned}
$$

In particular (exercise)

$$
\frac{\partial \log P_{\theta}(x)}{\partial \alpha_{k}}=P_{\theta}(Y=k \mid x)-\pi_{k}
$$

## Relation to classification with generative models $(3 / 3)$

The first $p$ elements in the Fisher score are given by class posteriors minus a constant

$$
\varphi_{\theta}(x)=\left[P_{\theta}(Y=1 \mid x)-\pi_{1}, \ldots, P_{\theta}(Y=p \mid x)-\pi_{p}, \ldots\right] .
$$

Consider a multi-class linear classifier on $\varphi_{\theta}(x)$ such that for class $k$

- The weights are zero except one for the $k$-th position;
- The intercept $b_{k}$ be $\pi_{k}$;

Then,

$$
\begin{aligned}
& \hat{y}(x)=\underset{k=1, \ldots, p}{\operatorname{argmax}} \varphi_{\theta}(x)^{\top} \mathbf{w}_{k}+b_{k} \\
& \hat{y}(x)=\underset{k=1, \ldots, p}{\operatorname{argmax}} P_{\theta}(Y=k \mid x) .
\end{aligned}
$$

Bayes' rule is implemented via this simple classifier using Fisher kernel.

## Outline

44 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Kernels for probabilistic models
- Fisher kernel
- Mutual information kernels
- Marginalized kernels
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Mutual information kernels

## Definition

- Chose a prior $w(d \theta)$ on the measurable set $\Theta$.
- Form the kernel (Seeger, 2002):

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\int_{\theta \in \Theta} P_{\theta}(\mathbf{x}) P_{\theta}\left(\mathbf{x}^{\prime}\right) w(d \theta) .
$$

- No explicit computation of a finite-dimensional feature vector.
- $K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=<\varphi(\mathbf{x}), \varphi\left(\mathbf{x}^{\prime}\right)>_{L_{2}(w)}$ with

$$
\varphi(\mathbf{x})=\left(P_{\theta}(\mathbf{x})\right)_{\theta \in \Theta} .
$$

## Example: coin toss

- Let $P_{\theta}(X=1)=\theta$ and $P_{\theta}(X=0)=1-\theta$ a model for random coin toss, with $\theta \in[0,1]$.
- Let $d \theta$ be the Lebesgue measure on $[0,1]$
- The mutual information kernel between $x=001$ and $x^{\prime}=1010$ is:

$$
\begin{gathered}
\left\{\begin{array}{l}
P_{\theta}(\mathbf{x})=\theta(1-\theta)^{2}, \\
P_{\theta}\left(\mathbf{x}^{\prime}\right)=\theta^{2}(1-\theta)^{2},
\end{array}\right. \\
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\int_{0}^{1} \theta^{3}(1-\theta)^{4} d \theta=\frac{3!4!}{8!}=\frac{1}{280} .
\end{gathered}
$$

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Kernels for probabilistic models
- Fisher kernel
- Mutual information kernels
- Marginalized kernels
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs

## Marginalized kernels

## Definition

- For any observed data $\mathbf{x} \in \mathcal{X}$, let a latent variable $\mathbf{y} \in \mathcal{Y}$ be associated probabilistically through a conditional probability $P_{\mathrm{x}}(\mathrm{d} \mathbf{y})$.
- Let $K_{\mathcal{Z}}$ be a kernel for the complete data $\mathbf{z}=(\mathbf{x}, \mathbf{y})$
- Then, the following kernel is a valid kernel on $\mathcal{X}$, called a marginalized kernel (Tsuda et al., 2002):

$$
\begin{aligned}
K_{\mathcal{X}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) & :=E_{P_{\mathbf{x}}(d \mathbf{y}) \times P_{\mathbf{x}^{\prime}}\left(d \mathbf{y}^{\prime}\right)} K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right) \\
& =\iint K_{\mathcal{Z}}\left((\mathbf{x}, \mathbf{y}),\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right) P_{\mathbf{x}}(d \mathbf{y}) P_{\mathbf{x}^{\prime}}\left(d \mathbf{y}^{\prime}\right) .
\end{aligned}
$$

## Marginalized kernels: proof of positive definiteness

- $K_{\mathcal{Z}}$ is p.d. on $\mathcal{Z}$. Therefore, there exists a Hilbert space $\mathcal{H}$ and $\Phi_{\mathcal{Z}}: \mathcal{Z} \rightarrow \mathcal{H}$ such that:

$$
K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right)=\left\langle\Phi_{\mathcal{Z}}(\mathbf{z}), \Phi_{\mathcal{Z}}\left(\mathbf{z}^{\prime}\right)\right\rangle_{\mathcal{H}} .
$$

- Marginalizing therefore gives:

$$
\begin{aligned}
K_{\mathcal{X}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) & =E_{P_{x}(d \mathbf{y}) \times P_{x^{\prime}}\left(d \mathbf{y}^{\prime}\right)} K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right) \\
& =E_{P_{x}(d \mathbf{y}) \times P_{\mathbf{x}^{\prime}}\left(d \mathbf{y}^{\prime}\right)}\left\langle\Phi_{\mathcal{Z}}(\mathbf{z}), \Phi_{\mathcal{Z}}\left(\mathbf{z}^{\prime}\right)\right\rangle_{\mathcal{H}} \\
& =\left\langle E_{P_{\mathrm{x}}(d \mathbf{y})} \Phi_{\mathcal{Z}}(\mathbf{z}), E_{P_{\mathbf{x}^{\prime}}\left(d \mathbf{y}^{\prime}\right)} \Phi_{\mathcal{Z}}\left(\mathbf{z}^{\prime}\right)\right\rangle_{\mathcal{H}}
\end{aligned}
$$

therefore $K_{\mathcal{X}}$ is p.d. on $\mathcal{X} . \square$

## Marginalized kernels: proof of positive definiteness

- $K_{\mathcal{Z}}$ is p.d. on $\mathcal{Z}$. Therefore, there exists a Hilbert space $\mathcal{H}$ and $\Phi_{\mathcal{Z}}: \mathcal{Z} \rightarrow \mathcal{H}$ such that:

$$
K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right)=\left\langle\Phi_{\mathcal{Z}}(\mathbf{z}), \Phi_{\mathcal{Z}}\left(\mathbf{z}^{\prime}\right)\right\rangle_{\mathcal{H}} .
$$

- Marginalizing therefore gives:

$$
\begin{aligned}
K_{\mathcal{X}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) & =E_{P_{x}(d \mathbf{y}) \times P_{x^{\prime}}\left(d \mathbf{y}^{\prime}\right)} K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right) \\
& =E_{P_{x}(d \mathbf{y}) \times P_{\mathbf{x}^{\prime}}\left(d \mathbf{y}^{\prime}\right)}\left\langle\Phi_{\mathcal{Z}}(\mathbf{z}), \Phi_{\mathcal{Z}}\left(\mathbf{z}^{\prime}\right)\right\rangle_{\mathcal{H}} \\
& =\left\langle E_{P_{\mathbf{x}}(d \mathbf{y})} \Phi_{\mathcal{Z}}(\mathbf{z}), E_{P_{x^{\prime}}\left(d \mathbf{y}^{\prime}\right)} \Phi_{\mathcal{Z}}\left(\mathbf{z}^{\prime}\right)\right\rangle_{\mathcal{H}}
\end{aligned}
$$

therefore $K_{\mathcal{X}}$ is p.d. on $\mathcal{X} . \quad \square$
Of course, we make the right assumptions such that each operation above is valid, and all quantities are well defined.

## Short history of genomics

1866 : Laws of heredity (Mendel)
1909 : Morgan and the drosophilists
1944 : DNA supports heredity (Avery)
1953: Structure of DNA (Crick, Watson, Wilkins and Franklin)
1966: Genetic code (Nirenberg)
1960-70 : Genetic engineering
1977: Method for sequencing (Sanger)
1982 : Creation of Genbank
1990 : Human genome project launched 2003: Human genome project completed

## A cell

## Chromosomes

## Chromosomes and DNA

## Structure of DNA

"We wish to suggest a structure for the salt of desoxyribose nucleic acid (D.N.A.). This structure have novel features which are of considerable biological interest" (Watson and Crick, 1953).

James Watson, Francis Crick, and Maurice Wilkins received the Nobel prize for this discovery in 1962. Key to this discovery were the X-ray crystallography images obtained by Rosalind Franklin.

## Structure of DNA

## The double helix

## Central dogma

## Proteins

## Genetic code

## DNA $=4$ letters (ATCG)

The Genetic Code

Protein $=20$ letters (amino acids)

## 1 amino acid

=
3 nucleotides

## Human genome project

- Goal : sequence the 3,000,000,000 bases of the human genome
- Consortium with 20 labs, 6 countries
- Cost : between 0.5 and 1 billion USD

## 2003: End of genomics era

## Findings

- About 25,000 genes only (representing $1.2 \%$ of the genome).
- Automatic gene finding with graphical models.
- $97 \%$ of the genome is considered "junk DNA".
- Superposition of a variety of signals (many to be discovered).

## Cost of human genome sequencing

## Cost per Genome

## Challenges with protein sequences

- A protein sequences can be seen as a variable-length sequence over the 20-letter alphabet of amino-acids, e.g., insuline: FVNQHLCGSHLVEALYLVCGERGFFYTPKA
- These sequences are produced at a fast rate (result of the sequencing programs)
- Need for algorithms to compare, classify, analyze these sequences
- Applications: classification into functional or structural classes, prediction of cellular localization and interactions, ...

## Example: supervised sequence classification

## Data (training)

- Secreted proteins: MASKATLLLAFTLLFATCIARHQQRQQQQNQCQLQNIEA. . . MARSSLFTFLCLAVFINGCLSQIEQQSPWEFQGSEVW . . . MALHTVLIMLSLLPMLEAQNPEHANITIGEPITNETLGWL. . .
- Non-secreted proteins: MAPPSVFAEVPQAQPVLVFKLIADFREDPDPRKVNLGVG . . . MAHTLGLTQPNSTEPHKISFTAKEIDVIEWKGDILVVG. . . MSISESYAKEIKTAFRQFTDFPIEGEQFEDFLPIIGNP. .

## Goal

- Build a classifier to predict whether new proteins are secreted or not.

## Supervised classification with vector embedding

## The idea

- Map each string $\mathbf{x} \in \mathcal{X}$ to a vector $\Phi(\mathbf{x}) \in \mathcal{F}$.
- Train a classifier for vectors on the images $\Phi\left(\mathbf{x}_{1}\right), \ldots, \Phi\left(\mathbf{x}_{n}\right)$ of the training set (nearest neighbor, linear perceptron, logistic regression, support vector machine...)

## Kernels for protein sequences

- Kernel methods have been widely investigated since Jaakkola et al.'s seminal paper (1998).
- What is a good kernel?
- it should be mathematically valid (symmetric, p.d. or c.p.d.)
- fast to compute
- adapted to the problem (gives good performances)

## Kernel engineering for protein sequences

- Define a (possibly high-dimensional) feature space of interest
- Physico-chemical kernels
- Spectrum, mismatch, substring kernels
- Pairwise, motif kernels

## Kernel engineering for protein sequences

- Define a (possibly high-dimensional) feature space of interest
- Physico-chemical kernels
- Spectrum, mismatch, substring kernels
- Pairwise, motif kernels
- Derive a kernel from a generative model
- Fisher kernel
- Mutual information kernel
- Marginalized kernel

## Kernel engineering for protein sequences

## Vector embedding for strings

The idea
Represent each sequence $\mathbf{x}$ by a fixed-length numerical vector $\Phi(x) \in \mathbb{R}^{n}$. How to perform this embedding?

## Vector embedding for strings

## The idea

Represent each sequence $\mathbf{x}$ by a fixed-length numerical vector $\Phi(\mathbf{x}) \in \mathbb{R}^{n}$. How to perform this embedding?

## Physico-chemical kernel

Extract relevant features, such as:

- length of the sequence
- time series analysis of numerical physico-chemical properties of amino-acids along the sequence (e.g., polarity, hydrophobicity), using for example:
- Fourier transforms (Wang et al., 2004)
- Autocorrelation functions (Zhang et al., 2003)

$$
r_{j}=\frac{1}{n-j} \sum_{i=1}^{n-j} h_{i} h_{i+j}
$$

## Substring indexation

## The approach

Alternatively, index the feature space by fixed-length strings, i.e.,

$$
\Phi(\mathbf{x})=\left(\Phi_{u}(\mathbf{x})\right)_{u \in \mathcal{A}^{k}}
$$

where $\Phi_{u}(\mathbf{x})$ can be:

- the number of occurrences of $u$ in $\mathbf{x}$ (without gaps) : spectrum kernel (Leslie et al., 2002)
- the number of occurrences of $u$ in $\mathbf{x}$ up to $m$ mismatches (without gaps) : mismatch kernel (Leslie et al., 2004)
- the number of occurrences of $u$ in $\mathbf{x}$ allowing gaps, with a weight decaying exponentially with the number of gaps: substring kernel (Lohdi et al., 2002)

## Example: Spectrum kernel (1/4)

## Kernel definition

- The 3 -spectrum of

$$
\mathbf{x}=\text { CGGSLIAMMWFGV }
$$

is:
(CGG , GGS , GSL , SLI , LIA , IAM , AMM , MMW , MWF , WFG , FGV) .

- Let $\Phi_{u}(\mathbf{x})$ denote the number of occurrences of $u$ in $\mathbf{x}$. The $k$-spectrum kernel is:

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right):=\sum_{u \in \mathcal{A}^{k}} \Phi_{u}(\mathbf{x}) \Phi_{u}\left(\mathbf{x}^{\prime}\right)
$$

## Example: Spectrum kernel (2/4)

## Implementation

- The computation of the kernel is formally a sum over $|\mathcal{A}|^{k}$ terms, but at most $|\mathbf{x}|-k+1$ terms are non-zero in $\Phi(\mathbf{x}) \Longrightarrow$ Computation in $O\left(|x|+\left|x^{\prime}\right|\right)$ with pre-indexation of the strings.
- Fast classification of a sequence $\mathbf{x}$ in $O(|\mathbf{x}|)$ :

$$
f(\mathbf{x})=\mathbf{w} \cdot \Phi(\mathbf{x})=\sum_{u} w_{u} \Phi_{u}(\mathbf{x})=\sum_{i=1}^{|\mathbf{x}|-k+1} w_{x_{i} \ldots x_{i+k-1}} .
$$

## Remarks

- Work with any string (natural language, time series...)
- Fast and scalable, a good default method for string classification.
- Variants allow matching of $k$-mers up to $m$ mismatches.

## Example: Spectrum kernel $(3 / 4)$

If pre-indexation is not possible: retrieval tree (trie)
Consider the sequence ACGTTTAACGTAC.

The complexity for computing $K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)$ becomes $O\left(k\left(|\mathbf{x}|+\left|\mathbf{x}^{\prime}\right|\right)\right)$.

## Example: Spectrum kernel (4/4)

If pre-indexation is not possible: use a suffix tree

The complexity for computing $K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)$ becomes $O\left(|\mathbf{x}|+\left|\mathbf{x}^{\prime}\right|\right)$, but with a larger constant than with pre-indexation.

## Example 2: Substring kernel $(1 / 12)$

## Definition

- For $1 \leq k \leq n \in \mathbb{N}$, we denote by $\mathcal{I}(k, n)$ the set of sequences of indices $\mathbf{i}=\left(i_{1}, \ldots, i_{k}\right)$, with $1 \leq i_{1}<i_{2}<\ldots<i_{k} \leq n$.
- For a string $\mathbf{x}=x_{1} \ldots x_{n} \in \mathcal{X}$ of length $n$, for a sequence of indices $\mathbf{i} \in \mathcal{I}(k, n)$, we define a substring as:

$$
\mathbf{x}(\mathbf{i}):=x_{i_{1}} x_{i_{2}} \ldots x_{i_{k}} .
$$

- The length of the substring is:

$$
I(\mathbf{i})=i_{k}-i_{1}+1
$$

## Example 2: Substring kernel $(2 / 12)$

## Example

## ABRACADABRA

- $\mathbf{i}=(3,4,7,8,10)$
- $\mathbf{x}(\mathbf{i})=$ RADAR
- $/(\mathbf{i})=10-3+1=8$

## Example 2: Substring kernel $(3 / 12)$

## The kernel

- Let $k \in \mathbb{N}$ and $\lambda \in \mathbb{R}^{+}$fixed. For all $\mathbf{u} \in \mathcal{A}^{k}$, let $\Phi_{\mathbf{u}}: \mathcal{X} \rightarrow \mathbb{R}$ be defined by:

$$
\forall \mathbf{x} \in \mathcal{X}, \quad \Phi_{\mathbf{u}}(\mathbf{x})=\sum_{\mathbf{i} \in \mathcal{I}(k,|\mathbf{x}|):} \lambda_{\mathbf{x}(\mathbf{i})=\mathbf{u}} \lambda^{\prime(\mathbf{i})} .
$$

- The substring kernel is the p.d. kernel defined by:

$$
\forall\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \in \mathcal{X}^{2}, \quad K_{k, \lambda}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{\mathbf{u} \in \mathcal{A}^{k}} \Phi_{\mathbf{u}}(\mathbf{x}) \Phi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right) .
$$

## Example 2: Substring kernel $(4 / 12)$

## Example

| u | ca | ct | at | ba | bt | cr | ar | br |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\Phi_{u}(\mathrm{cat})$ | $\lambda^{2}$ | $\lambda^{3}$ | $\lambda^{2}$ | 0 | 0 | 0 | 0 | 0 |
| $\Phi_{u}(\mathrm{car})$ | $\lambda^{2}$ | 0 | 0 | 0 | 0 | $\lambda^{3}$ | $\lambda^{2}$ | 0 |
| $\Phi_{u}($ bat $)$ | 0 | 0 | $\lambda^{2}$ | $\lambda^{2}$ | $\lambda^{3}$ | 0 | 0 | 0 |
| $\Phi_{u}(\mathrm{bar})$ | 0 | 0 | 0 | $\lambda^{2}$ | 0 | 0 | $\lambda^{2}$ | $\lambda^{3}$ |

$$
\left\{\begin{array}{l}
K(\text { cat }, \text { cat })=K(c a r, c a r)=2 \lambda^{4}+\lambda^{6} \\
K(\text { cat }, \text { car })=\lambda^{4} \\
K(\text { cat }, \text { bar })=0
\end{array}\right.
$$

## Example 2: Substring kernel $(5 / 12)$

## Kernel computation

- We need to compute, for any pair $\mathbf{x}, \mathbf{x}^{\prime} \in \mathcal{X}$, the kernel:

$$
\begin{aligned}
K_{k, \lambda}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) & =\sum_{\mathbf{u} \in \mathcal{A}^{k}} \Phi_{\mathbf{u}}(\mathbf{x}) \Phi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right) \\
& =\sum_{\mathbf{u} \in \mathcal{A}^{k}} \sum_{\mathrm{i}: \times(\mathrm{i})=\mathbf{u} \mathrm{i}^{\prime}: x^{\prime}\left(\mathrm{i}^{\prime}\right)=\mathbf{u}} \lambda^{/(\mathrm{i})+/\left(\mathrm{i}^{\prime}\right)} .
\end{aligned}
$$

- Enumerating the substrings is too slow (of order $|\mathbf{x}|^{k}$ ).

## Example 2: Substring kernel $(6 / 12)$

## Kernel computation (cont.)

- For $\mathbf{u} \in \mathcal{A}^{k}$ remember that:

$$
\Phi_{\mathbf{u}}(\mathbf{x})=\sum_{\mathbf{i}: \mathbf{x}(\mathbf{i})=\mathbf{u}} \lambda^{i_{k}-i_{1}+1}
$$

- Let now:

$$
\Psi_{\mathbf{u}}(\mathbf{x})=\sum_{\mathbf{i}: \mathbf{x}(\mathbf{i})=\mathbf{u}} \lambda^{|\mathbf{x}|-i_{1}+1}
$$

## Example 2: Substring kernel $(7 / 12)$

## Kernel computation (cont.)

Let us note $\mathbf{x}_{[1, j]}=x_{1} \ldots x_{j}$. A simple rewriting shows that, if we note $a \in \mathcal{A}$ the last letter of $\mathbf{u}(\mathbf{u}=\mathbf{v} a)$ :

$$
\Phi_{\mathbf{v a}}(\mathbf{x})=\sum_{j \in[1,|\mathbf{x}|]: x_{j}=a} \Psi_{\mathbf{v}}\left(\mathbf{x}_{[1, j-1]}\right) \lambda,
$$

and

$$
\Psi_{\mathrm{va}}(\mathbf{x})=\sum_{j \in[1,|\mathrm{x}|]: x_{j}=a} \Psi_{\mathbf{v}}\left(\mathbf{x}_{[1, j-1]}\right) \lambda^{|\mathbf{x}|-j+1}
$$

## Example 2: Substring kernel $(8 / 12)$

## Kernel computation (cont.)

Moreover we observe that if the string is of the form $\mathbf{x a}$ (i.e., the last letter is $a \in \mathcal{A}$ ), then:

- If the last letter of $\mathbf{u}$ is not $a$ :

$$
\left\{\begin{array}{l}
\Phi_{\mathbf{u}}(\mathbf{x} a)=\Phi_{\mathbf{u}}(\mathbf{x}) \\
\Psi_{\mathbf{u}}(\mathbf{x} a)=\lambda \Psi_{\mathbf{u}}(\mathbf{x})
\end{array}\right.
$$

- If the last letter of $\mathbf{u}$ is a (i.e., $\mathbf{u}=\mathbf{v a}$ with $\mathbf{v} \in \mathcal{A}^{k-1}$ ):

$$
\left\{\begin{array}{l}
\Phi_{\mathrm{va}}(\mathbf{x} a)=\Phi_{\mathrm{va}}(\mathbf{x})+\lambda \Psi_{\mathbf{v}}(\mathbf{x}) \\
\Psi_{\mathrm{va}}(\mathbf{x} a)=\lambda \Psi_{\mathrm{va}}(\mathbf{x})+\lambda \Psi_{\mathbf{v}}(\mathbf{x})
\end{array}\right.
$$

## Example 2: Substring kernel $(9 / 12)$

## Kernel computation (cont.)

Let us now show how the function:

$$
B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right):=\sum_{\mathbf{u} \in \mathcal{A}^{k}} \Psi_{\mathbf{u}}(\mathbf{x}) \Psi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right)
$$

and the kernel:

$$
K_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right):=\sum_{\mathbf{u} \in \mathcal{A}^{k}} \Phi_{\mathbf{u}}(\mathbf{x}) \Phi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right)
$$

can be computed recursively. We note that:

$$
\begin{cases}B_{0}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=K_{0}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=1 & \text { for all } \mathbf{x}, \mathbf{x}^{\prime} \\ B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=K_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=0 & \text { if } \min \left(|\mathbf{x}|,\left|\mathbf{x}^{\prime}\right|\right)<k\end{cases}
$$

## Example 2: Substring kernel $(10 / 12)$

## Recursive computation of $B_{k}$

$$
\begin{aligned}
& B_{k}\left(\mathbf{x a ,}, \mathbf{x}^{\prime}\right) \\
&= \sum_{\mathbf{u} \in \mathcal{A}^{k}} \Psi_{\mathbf{u}}(\mathbf{x a}) \Psi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right) \\
&= \lambda \sum_{\mathbf{u} \in \mathcal{A}^{k}} \Psi_{\mathbf{u}}(\mathbf{x}) \Psi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right)+\lambda \sum_{\mathbf{v} \in \mathcal{A}^{k-1}} \Psi_{\mathbf{v}}(\mathbf{x}) \Psi_{\mathbf{v a}}\left(\mathbf{x}^{\prime}\right) \\
&= \lambda B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)+ \\
& \lambda \sum_{\mathbf{v} \in \mathcal{A}^{k-1}} \Psi_{\mathbf{v}}(\mathbf{x})\left(\sum_{j \in\left[1,\left|\mathbf{x}^{\prime}\right|\right]: x_{j}^{\prime}=a} \Psi_{\mathbf{v}}\left(\mathbf{x}_{[1, j-1]}^{\prime}\right) \lambda^{\left|\mathbf{x}^{\prime}\right|-j+1}\right) \\
&= \lambda B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)+\sum_{j \in\left[1,\left|\mathbf{x}^{\prime}\right|\right]: x_{j}^{\prime}=a} B_{k-1}\left(\mathbf{x}, \mathbf{x}_{[1, j-1]}^{\prime}\right) \lambda^{\left|\mathbf{x}^{\prime}\right|-j+2}
\end{aligned}
$$

## Example 2: Substring kernel $(11 / 12)$

## Recursive computation of $B_{k}$

$$
\begin{aligned}
& B_{k}\left(\mathbf{x} a, \mathbf{x}^{\prime} b\right) \\
& =\lambda B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime} b\right)+\lambda \sum_{j \in\left[1,\left|\mathbf{x}^{\prime}\right|\right]: x_{j}^{\prime}=a} B_{k-1}\left(\mathbf{x}, \mathbf{x}_{[1, j-1]}^{\prime}\right) \lambda^{\left|\mathbf{x}^{\prime}\right|-j+2} \\
& +\delta_{a=b} B_{k-1}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \lambda^{2}
\end{aligned} \begin{aligned}
& =\lambda B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime} b\right)+\lambda\left(B_{k}\left(\mathbf{x} a, \mathbf{x}^{\prime}\right)-\lambda B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)\right)+\delta_{a=b} B_{k-1}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \lambda^{2} \\
& =\lambda B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime} b\right)+\lambda B_{k}\left(\mathbf{x} a, \mathbf{x}^{\prime}\right)-\lambda^{2} B_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)+\delta_{a=b} B_{k-1}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \lambda^{2} .
\end{aligned}
$$

The dynamic programming table can be filled in $O\left(k|\mathbf{x}|\left|\mathbf{x}^{\prime}\right|\right)$ operations.

## Example 2: Substring kernel $(12 / 12)$

## Recursive computation of $K_{k}$

$$
\begin{aligned}
& K_{k}\left(\mathbf{x a}, \mathbf{x}^{\prime}\right) \\
& =\sum_{\mathbf{u} \in \mathcal{A}^{k}} \Phi_{\mathbf{u}}(\mathbf{x a}) \Phi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right) \\
& =\sum_{\mathbf{u} \in \mathcal{A}^{k}} \Phi_{\mathbf{u}}(\mathbf{x}) \Phi_{\mathbf{u}}\left(\mathbf{x}^{\prime}\right)+\lambda \sum_{\mathbf{v} \in \mathcal{A}^{k}-1} \Psi_{\mathbf{v}}(\mathbf{x}) \Phi_{\mathbf{v a}}\left(\mathbf{x}^{\prime}\right) \\
& =K_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)+ \\
& \\
& \quad \lambda \sum_{\mathbf{v} \in \mathcal{A}^{k}-1} \Psi_{\mathbf{v}}(\mathbf{x})\left(\sum_{j \in\left[1, \mid \mathbf{x}^{\prime}\right]: x_{j}^{\prime}=a} \Psi_{\mathbf{v}}\left(\mathbf{x}_{[1, j-1]}^{\prime}\right) \lambda\right) \\
& =K_{k}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)+\lambda^{2} \sum_{j \in\left[1,\left|\mathbf{x}^{\prime}\right|\right]: x_{j}^{\prime}=a} B_{k-1}\left(\mathbf{x}, \mathbf{x}_{[1, j-1]}^{\prime}\right)
\end{aligned}
$$

## Summary: Substring indexation

- Implementation in $O\left(|\mathbf{x}|+\left|\mathbf{x}^{\prime}\right|\right)$ in memory and time for the spectrum and mismatch kernels (with suffix trees)
- Implementation in $O\left(k\left(|\mathbf{x}|+\left|\mathbf{x}^{\prime}\right|\right)\right)$ in memory and time for the spectrum and mismatch kernels (with tries)
- Implementation in $O\left(k|\mathbf{x}| \times\left|\mathbf{x}^{\prime}\right|\right)$ in memory and time for the substring kernels
- The feature space has high dimension $\left(|\mathcal{A}|^{k}\right)$, so learning requires regularized methods (such as SVM)

## Dictionary-based indexation

The approach

- Chose a dictionary of sequences $\mathcal{D}=\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right)$
- Chose a measure of similarity $s\left(\mathbf{x}, \mathbf{x}^{\prime}\right)$
- Define the mapping $\Phi_{\mathcal{D}}(\mathbf{x})=\left(s\left(\mathbf{x}, \mathbf{x}_{i}\right)\right)_{\mathbf{x}_{i} \in \mathcal{D}}$

## Dictionary-based indexation

## The approach

- Chose a dictionary of sequences $\mathcal{D}=\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right)$
- Chose a measure of similarity $s\left(\mathbf{x}, \mathbf{x}^{\prime}\right)$
- Define the mapping $\Phi_{\mathcal{D}}(\mathbf{x})=\left(s\left(\mathbf{x}, \mathbf{x}_{i}\right)\right)_{\mathbf{x}_{i} \in \mathcal{D}}$

## Examples

This includes:

- Motif kernels (Logan et al., 2001): the dictionary is a library of motifs, the similarity function is a matching function
- Pairwise kernel (Liao \& Noble, 2003): the dictionary is the training set, the similarity is a classical measure of similarity between sequences.

## Outline

4 The Kernel Jungle

- Kernels on graphs

## Probabilistic models for sequences

Probabilistic modeling of biological sequences is older than kernel designs. Important models include HMM for protein sequences, SCFG for RNA sequences.

Recall: parametric model
A model is a family of distributions

$$
\left\{P_{\theta}, \theta \in \Theta \subset \mathbb{R}^{m}\right\} \subset \mathcal{M}_{1}^{+}(\mathcal{X})
$$

## Context-tree model

## Definition

A context-tree model is a variable-memory Markov chain:

$$
P_{\mathcal{D}, \theta}(\mathbf{x})=P_{\mathcal{D}, \theta}\left(x_{1} \ldots x_{D}\right) \prod_{i=D+1}^{n} P_{\mathcal{D}, \theta}\left(x_{i} \mid x_{i-D} \ldots x_{i-1}\right)
$$

- $\mathcal{D}$ is a suffix tree
- $\theta \in \Sigma^{\mathcal{D}}$ is a set of conditional probabilities (multinomials)

## Context-tree model: example

$P(A A B A C B A C C)=P(A A B) \theta_{A B}(A) \theta_{A}(C) \theta_{C}(B) \theta_{A C B}(A) \theta_{A}(C) \theta_{C}(A)$.

## The context-tree kernel

## Theorem (Cuturi et al., 2005)

- For particular choices of priors, the context-tree kernel:

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{\mathcal{D}} \int_{\theta \in \Sigma_{\mathcal{D}}} P_{\mathcal{D}, \theta}(\mathbf{x}) P_{\mathcal{D}, \theta}\left(\mathbf{x}^{\prime}\right) w(d \theta \mid \mathcal{D}) \pi(\mathcal{D})
$$

can be computed in $O\left(|\mathbf{x}|+\left|\mathbf{x}^{\prime}\right|\right)$ with a variant of the Context-Tree Weighting algorithm.

- This is a valid mutual information kernel.
- The similarity is related to information-theoretical measure of mutual information between strings.

## Marginalized kernels

## Recall: Definition

- For any observed data $\mathbf{x} \in \mathcal{X}$, let a latent variable $\mathbf{y} \in \mathcal{Y}$ be associated probabilistically through a conditional probability $P_{\mathrm{x}}(\mathrm{d} \mathbf{y})$.
- Let $K_{\mathcal{Z}}$ be a kernel for the complete data $\mathbf{z}=(\mathbf{x}, \mathbf{y})$
- Then the following kernel is a valid kernel on $\mathcal{X}$, called a marginalized kernel (Tsuda et al., 2002):

$$
\begin{aligned}
K_{\mathcal{X}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) & :=E_{P_{\mathbf{x}}(d \mathbf{y}) \times P_{x^{\prime}}\left(d \mathbf{y}^{\prime}\right)} K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right) \\
& =\iint K_{\mathcal{Z}}\left((\mathbf{x}, \mathbf{y}),\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right) P_{\mathbf{x}}(d \mathbf{y}) P_{\mathbf{x}^{\prime}}\left(d \mathbf{y}^{\prime}\right) .
\end{aligned}
$$

## Example: HMM for normal/biased coin toss

- Normal ( $N$ ) and biased ( $B$ ) coins (not observed)
- Observed output are $0 / 1$ with probabilities:

$$
\left\{\begin{array}{l}
\pi(0 \mid N)=1-\pi(1 \mid N)=0.5 \\
\pi(0 \mid B)=1-\pi(1 \mid B)=0.2
\end{array}\right.
$$

- Example of realization (complete data):

NNNNNBBBBBBBBBNNNNNNNNNNNBBBBBB
1001011101111010010111001111011

## 1-spectrum kernel on complete data

- If both $\mathbf{x} \in \mathcal{A}^{*}$ and $\mathbf{y} \in \mathcal{S}^{*}$ were observed, we might rather use the 1 -spectrum kernel on the complete data $\mathbf{z}=(\mathbf{x}, \mathbf{y})$ :

$$
K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right)=\sum_{(a, s) \in \mathcal{A} \times \mathcal{S}} n_{a, s}(\mathbf{z}) n_{a, s}\left(\mathbf{z}^{\prime}\right),
$$

where $n_{a, s}(\mathbf{x}, \mathbf{y})$ for $a=0,1$ and $s=N, B$ is the number of occurrences of $s$ in $\mathbf{y}$ which emit $a$ in $\mathbf{x}$.

- Example:

$$
\begin{gathered}
\mathbf{z}=1001011101111010010111001111011 \\
\mathbf{z}^{\prime}=0011010110011111011010111101100101
\end{gathered}
$$

$$
\begin{aligned}
K_{\mathcal{Z}}\left(\mathbf{z}, \mathbf{z}^{\prime}\right) & =n_{1}(\mathbf{z}) n_{1}\left(\mathbf{z}^{\prime}\right)+n_{1}(\mathbf{z}) n_{1}\left(\mathbf{z}^{\prime}\right)+n_{0}(\mathbf{z}) n_{0}\left(\mathbf{z}^{\prime}\right)+n_{0}(\mathbf{z}) n_{0}\left(\mathbf{z}^{\prime}\right) \\
& =7 \times 15+13 \times 6+9 \times 12+2 \times 1=293
\end{aligned}
$$

## 1-spectrum marginalized kernel on observed data

- The marginalized kernel for observed data is:

$$
\begin{aligned}
K_{\mathcal{X}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) & =\sum_{\mathbf{y}, \mathbf{y}^{\prime} \in \mathcal{S}^{*}} K_{\mathcal{Z}}\left((\mathbf{x}, \mathbf{y}),\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right) P(\mathbf{y} \mid \mathbf{x}) P\left(\mathbf{y}^{\prime} \mid \mathbf{x}^{\prime}\right) \\
& =\sum_{(a, s) \in \mathcal{A} \times \mathcal{S}} \Phi_{a, s}(\mathbf{x}) \Phi_{a, s}\left(\mathbf{x}^{\prime}\right)
\end{aligned}
$$

with

$$
\Phi_{a, s}(\mathbf{x})=\sum_{\mathbf{y} \in \mathcal{S}^{*}} P(\mathbf{y} \mid \mathbf{x}) n_{a, s}(\mathbf{x}, \mathbf{y})
$$

## Computation of the 1-spectrum marginalized kernel

$$
\begin{aligned}
\Phi_{a, s}(\mathbf{x}) & =\sum_{\mathbf{y} \in \mathcal{S}^{*}} P(\mathbf{y} \mid \mathbf{x}) n_{a, s}(\mathbf{x}, \mathbf{y}) \\
& =\sum_{\mathbf{y} \in \mathcal{S}^{*}} P(\mathbf{y} \mid \mathbf{x})\left\{\sum_{i=1}^{n} \delta\left(x_{i}, a\right) \delta\left(y_{i}, s\right)\right\} \\
& =\sum_{i=1}^{n} \delta\left(x_{i}, a\right)\left\{\sum_{\mathbf{y} \in \mathcal{S}^{*}} P(\mathbf{y} \mid \mathbf{x}) \delta\left(y_{i}, s\right)\right\} \\
& =\sum_{i=1}^{n} \delta\left(x_{i}, a\right) P\left(y_{i}=s \mid \mathbf{x}\right) .
\end{aligned}
$$

and $P\left(y_{i}=s \mid \mathbf{x}\right)$ can be computed efficiently by forward-backward algorithm!

## HMM example (DNA)

## HMM example (protein)

## SCFG for RNA sequences

SFCG rules

- $S \rightarrow S S$
- $S \rightarrow a S a$
- $S \rightarrow a S$
- $S \rightarrow a$

Marginalized kernel (Kin et al., 2002)

- Feature: number of occurrences of each (base,state) combination
- Marginalization using classical inside/outside algorithm

## Marginalized kernels in practice

## Examples

- Spectrum kernel on the hidden states of a HMM for protein sequences (Tsuda et al., 2002)
- Kernels for RNA sequences based on SCFG (Kin et al., 2002)
- Kernels for graphs based on random walks on graphs (Kashima et al., 2004)
- Kernels for multiple alignments based on phylogenetic models (Vert et al., 2006)

## Marginalized kernels: example

A set of 74 human tRNA sequences is analyzed using a kernel for sequences (the second-order marginalized kernel based on SCFG). This set of tRNAs contains three classes, called Ala-AGC (white circles), Asn-GTT (black circles) and Cys-GCA (plus symbols) (from Tsuda et al., 2002).

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Kernels for probabilistic models
- Kernels for biological sequences
- Motivations and history of genomics
- Kernels derived from large feature spaces
- Kernels derived from generative models
- Kernels derived from a similarity measure
- Application to remote homology detection
- Kernels for graphs
- Kernels on graphs

## Sequence alignment

## Motivation

How to compare 2 sequences?

$$
\begin{gathered}
\mathbf{x}_{1}=\text { CGGSLIAMMWFGV } \\
\mathbf{x}_{2}=\text { CLIVMMNRLMWFGV }
\end{gathered}
$$

Find a good alignment:

$$
\begin{aligned}
& \text { CGGSLIAMM------WFGV } \\
& \text { |...|||||.....|||| } \\
& \text { C-----LIVMMNRLMWFGV }
\end{aligned}
$$

## Alignment score

In order to quantify the relevance of an alignment $\pi$, define:

- a substitution matrix $S \in \mathbb{R}^{\mathcal{A} \times \mathcal{A}}$
- a gap penalty function $g: \mathbb{N} \rightarrow \mathbb{R}$

Any alignment is then scored as follows

$$
\begin{gathered}
\text { CGGSLIAMM------WFGV } \\
\text { I . . . I III . . . . I I। I } \\
\text { C----LIVMMNRLMWFGV }
\end{gathered}
$$

$$
\begin{aligned}
s_{S, g}(\pi) & =S(C, C)+S(L, L)+S(I, I)+S(A, V)+2 S(M, M) \\
& +S(W, W)+S(F, F)+S(G, G)+S(V, V)-g(3)-g(4)
\end{aligned}
$$

## Local alignment kernel

## Smith-Waterman score (Smith and Waterman, 1981)

- The widely-used Smith-Waterman local alignment score is defined by:

$$
S W_{S, g}(\mathbf{x}, \mathbf{y}):=\max _{\pi \in \Pi(\mathbf{x}, \mathbf{y})} s_{S, g}(\pi)
$$

- It is symmetric, but not positive definite...

## Local alignment kernel

## Smith-Waterman score (Smith and Waterman, 1981)

- The widely-used Smith-Waterman local alignment score is defined by:

$$
S W_{S, g}(\mathbf{x}, \mathbf{y}):=\max _{\pi \in \Pi(\mathbf{x}, \mathbf{y})} s_{S, g}(\pi)
$$

- It is symmetric, but not positive definite...

LA kernel (Saigo et al., 2004)
The local alignment kernel:

$$
K_{L A}^{(\beta)}(\mathbf{x}, \mathbf{y})=\sum_{\pi \in \Pi(\mathbf{x}, \mathbf{y})} \exp \left(\beta s_{S, g}(\mathbf{x}, \mathbf{y}, \pi)\right)
$$

is symmetric positive definite.

## LA kernel is p.d.: proof $(1 / 11)$

## Lemma

- If $K_{1}$ and $K_{2}$ are p.d. kernels, then:

$$
\begin{aligned}
& K_{1}+K_{2}, \\
& \quad K_{1} K_{2}, \text { and } \\
& \quad c K_{1}, \text { for } c \geq 0
\end{aligned}
$$

are also p.d. kernels

- If $\left(K_{i}\right)_{i \geq 1}$ is a sequence of p.d. kernels that converges pointwisely to a function $K$ :

$$
\forall\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \in \mathcal{X}^{2}, \quad K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\lim _{n \rightarrow \infty} K_{i}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)
$$

then $K$ is also a p.d. kernel.

## LA kernel is p.d.: proof $(2 / 11)$

## Proof of lemma

Let $A$ and $B$ be $n \times n$ positive semidefinite matrices. By diagonalization of $A$ :

$$
A_{i, j}=\sum_{p=1}^{n} f_{p}(i) f_{p}(j)
$$

for some vectors $f_{1}, \ldots, f_{n}$. Then, for any $\boldsymbol{\alpha} \in \mathbb{R}^{n}$ :

$$
\sum_{i, j=1}^{n} \alpha_{i} \alpha_{j} A_{i, j} B_{i, j}=\sum_{p=1}^{n} \sum_{i, j=1}^{n} \alpha_{i} f_{p}(i) \alpha_{j} f_{p}(j) B_{i, j} \geq 0
$$

The matrix $C_{i, j}=A_{i, j} B_{i, j}$ is therefore p.d. Other properties are obvious from definition. $\square$

## LA kernel is p.d.: proof $(3 / 11)$

Lemma (direct sum and product of kernels)
Let $\mathcal{X}=\mathcal{X}_{1} \times \mathcal{X}_{2}$. Let $K_{1}$ be a p.d. kernel on $\mathcal{X}_{1}$, and $K_{2}$ be a p.d. kernel on $\mathcal{X}_{2}$. Then the following functions are p.d. kernels on $\mathcal{X}$ :

- the direct sum,

$$
K\left(\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right),\left(\mathbf{y}_{1}, \mathbf{y}_{2}\right)\right)=K_{1}\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right)+K_{2}\left(\mathbf{x}_{2}, \mathbf{y}_{2}\right),
$$

- The direct product:

$$
K\left(\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right),\left(\mathbf{y}_{1}, \mathbf{y}_{2}\right)\right)=K_{1}\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right) K_{2}\left(\mathbf{x}_{2}, \mathbf{y}_{2}\right) .
$$

## LA kernel is p.d.: proof $(4 / 11)$

## Proof of lemma

If $K_{1}$ is a p.d. kernel, let $\Phi_{1}: \mathcal{X}_{1} \mapsto \mathcal{H}$ be such that:

$$
K_{1}\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right)=\left\langle\Phi_{1}\left(\mathbf{x}_{1}\right), \Phi_{1}\left(\mathbf{y}_{1}\right)\right\rangle_{\mathcal{H}}
$$

Let $\Phi: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{H}$ be defined by:

$$
\Phi\left(\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right)\right)=\Phi_{1}\left(\mathbf{x}_{1}\right) .
$$

Then for $\mathbf{x}=\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right)$ and $\mathbf{y}=\left(\mathbf{y}_{1}, \mathbf{y}_{2}\right) \in \mathcal{X}$, we get

$$
\left\langle\Phi\left(\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right)\right), \Phi\left(\left(\mathbf{y}_{1}, \mathbf{y}_{2}\right)\right)\right\rangle_{\mathcal{H}}=K_{1}\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right),
$$

which shows that $K(\mathbf{x}, \mathbf{y}):=K_{1}\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right)$ is p.d. on $\mathcal{X}_{1} \times \mathcal{X}_{2}$. The lemma follows from the properties of sums and products of p.d. kernels.

## LA kernel is p.d.: proof $(5 / 11)$

## Lemma: kernel for sets

Let $K$ be a p.d. kernel on $\mathcal{X}$, and let $\mathcal{P}(\mathcal{X})$ be the set of finite subsets of $\mathcal{X}$. Then the function $K_{P}$ on $\mathcal{P}(\mathcal{X}) \times \mathcal{P}(\mathcal{X})$ defined by:

$$
\forall A, B \in \mathcal{P}(\mathcal{X}), \quad K_{P}(A, B):=\sum_{x \in A} \sum_{\mathbf{y} \in B} K(\mathbf{x}, \mathbf{y})
$$

is a p.d. kernel on $\mathcal{P}(\mathcal{X})$.

## LA kernel is p.d.: proof $(6 / 11)$

## Proof of lemma

Let $\Phi: \mathcal{X} \mapsto \mathcal{H}$ be such that

$$
K(\mathbf{x}, \mathbf{y})=\langle\Phi(\mathbf{x}), \Phi(\mathbf{y})\rangle_{\mathcal{H}} .
$$

Then, for $A, B \in \mathcal{P}(\mathcal{X})$, we get:

$$
\begin{aligned}
K_{P}(A, B) & =\sum_{\mathbf{x} \in A} \sum_{\mathbf{y} \in B}\langle\Phi(\mathbf{x}), \Phi(\mathbf{y})\rangle_{\mathcal{H}} \\
& =\left\langle\sum_{\mathbf{x} \in A} \Phi(\mathbf{x}), \sum_{\mathbf{y} \in B} \Phi(\mathbf{y})\right\rangle_{\mathcal{H}} \\
& =\left\langle\Phi_{P}(A), \Phi_{P}(B)\right\rangle_{\mathcal{H}},
\end{aligned}
$$

with $\Phi_{P}(A):=\sum_{\mathbf{x} \in A} \Phi(\mathbf{x})$.

## LA kernel is p.d.: proof $(7 / 11)$

## Definition: Convolution kernel (Haussler, 1999)

Let $K_{1}$ and $K_{2}$ be two p.d. kernels for strings. The convolution of $K_{1}$ and $K_{2}$, denoted $K_{1} \star K_{2}$, is defined for any $\mathbf{x}, \mathbf{x}^{\prime} \in \mathcal{X}$ by:

$$
K_{1} \star K_{2}(\mathbf{x}, \mathbf{y}):=\sum_{x_{1} x_{2}=x, y_{1} y_{2}=y} K_{1}\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right) K_{2}\left(\mathbf{x}_{2}, \mathbf{y}_{2}\right) .
$$

## Lemma

If $K_{1}$ and $K_{2}$ are p.d. then $K_{1} \star K_{2}$ is p.d..

## LA kernel is p.d.: proof $(8 / 11)$

## Proof of lemma

Let $\mathcal{X}$ be the set of finite-length strings. For $\mathbf{x} \in \mathcal{X}$, let

$$
R(\mathbf{x})=\left\{\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right) \in \mathcal{X} \times \mathcal{X}: \mathbf{x}=\mathbf{x}_{1} \mathbf{x}_{2}\right\} \subset \mathcal{X} \times \mathcal{X}
$$

We can then write

$$
K_{1} \star K_{2}(\mathbf{x}, \mathbf{y})=\sum_{\left(\mathbf{x}_{1}, \mathbf{x}_{2}\right) \in R(\mathbf{x})} \sum_{\left(\mathbf{y}_{1}, \mathbf{y}_{2}\right) \in R(\mathbf{y})} K_{1}\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right) K_{2}\left(\mathbf{x}_{2}, \mathbf{y}_{2}\right)
$$

which is a p.d. kernel by the previous lemmas.

## LA kernel is p.d.: proof $(9 / 11)$

## 3 basic string kernels

- The constant kernel:

$$
K_{0}(\mathbf{x}, \mathbf{y}):=1 .
$$

- A kernel for letters:

$$
K_{a}^{(\beta)}(\mathbf{x}, \mathbf{y}):= \begin{cases}0 & \text { if }|\mathbf{x}| \neq 1 \text { where }|\mathbf{y}| \neq 1 \\ \exp (\beta S(\mathbf{x}, \mathbf{y})) & \text { otherwise } .\end{cases}
$$

- A kernel for gaps:

$$
K_{g}^{(\beta)}(\mathbf{x}, \mathbf{y})=\exp [\beta(g(|\mathbf{x}|)+g(|\mathbf{y}|))] .
$$

## LA kernel is p.d.: proof $(10 / 11)$

## Remark

- $S: \mathcal{A}^{2} \rightarrow \mathbb{R}$ is the similarity function between letters used in the alignment score. $K_{a}^{(\beta)}$ is only p.d. when the matrix:

$$
(\exp (\beta s(a, b)))_{(a, b) \in \mathcal{A}^{2}}
$$

is positive semidefinite (this is true for all $\beta$ when $s$ is conditionally p.d..

- $g$ is the gap penalty function used in alignment score. The gap kernel is always p.d. (with no restriction on $g$ ) because it can be written as:

$$
K_{g}^{(\beta)}(\mathbf{x}, \mathbf{y})=\exp (\beta g(|\mathbf{x}|)) \times \exp (\beta g(|\mathbf{y}|))
$$

## LA kernel is p.d.: proof $(11 / 11)$

## Lemma

The local alignment kernel is a (limit) of convolution kernel:

$$
K_{L A}^{(\beta)}=\sum_{n=0}^{\infty} K_{0} \star\left(K_{a}^{(\beta)} \star K_{g}^{(\beta)}\right)^{(n-1)} \star K_{a}^{(\beta)} \star K_{0} .
$$

As such it is p.d..

## Proof (sketch)

- By induction on $n$ (simple but long to write).
- See details in Vert et al. (2004).

## LA kernel computation

- We assume an affine gap penalty:

$$
\left\{\begin{array}{l}
g(0)=0 \\
g(n)=d+e(n-1) \text { si } n \geq 1
\end{array}\right.
$$

- The LA kernel can then be computed by dynamic programming by:

$$
K_{L A}^{(\beta)}(\mathbf{x}, \mathbf{y})=1+X_{2}(|\mathbf{x}|,|\mathbf{y}|)+Y_{2}(|\mathbf{x}|,|\mathbf{y}|)+M(|\mathbf{x}|,|\mathbf{y}|),
$$

where $M(i, j), X(i, j), Y(i, j), X_{2}(i, j)$, and $Y_{2}(i, j)$ for $0 \leq i \leq|\mathbf{x}|$, and $0 \leq j \leq|y|$ are defined recursively.

## LA kernel is p.d.: proof (/)

## Initialization

$$
\left\{\begin{array}{l}
M(i, 0)=M(0, j)=0, \\
X(i, 0)=X(0, j)=0, \\
Y(i, 0)=Y(0, j)=0, \\
X_{2}(i, 0)=X_{2}(0, j)=0, \\
Y_{2}(i, 0)=Y_{2}(0, j)=0,
\end{array}\right.
$$

## LA kernel is p.d.: proof (/)

## Recursion

For $i=1, \ldots,|\mathbf{x}|$ and $j=1, \ldots,|\mathbf{y}|$ :

$$
\left\{\begin{aligned}
M(i, j)= & \exp \left(\beta S\left(x_{i}, y_{j}\right)\right)[1+X(i-1, j-1) \\
& \quad+Y(i-1, j-1)+M(i-1, j-1)], \\
X(i, j) & =\exp (\beta d) M(i-1, j)+\exp (\beta e) X(i-1, j), \\
Y(i, j) & =\exp (\beta d)[M(i, j-1)+X(i, j-1)] \\
& \quad+\exp (\beta e) Y(i, j-1), \\
X_{2}(i, j)= & M(i-1, j)+X_{2}(i-1, j), \\
Y_{2}(i, j)= & M(i, j-1)+X_{2}(i, j-1)+Y_{2}(i, j-1) .
\end{aligned}\right.
$$

## LA kernel in practice

- Implementation by a finite-state transducer in $O\left(|\mathbf{x}| \times\left|\mathbf{x}^{\prime}\right|\right)$

- In practice, values are too large (exponential scale) so taking its logarithm is a safer choice (but not p.d. anymore!)

## Remote homology

Sequence similarity

- Homologs have common ancestors
- Structures and functions are more conserved than sequences
- Remote homologs can not be detected by direct sequence comparison

## SCOP database

## A benchmark experiment

- Goal: recognize directly the superfamily
- Training: for a sequence of interest, positive examples come from the same superfamily, but different families. Negative from other superfamilies.
- Test: predict the superfamily.

## Difference in performance

Performance on the SCOP superfamily recognition benchmark (from Saigo et al., 2004).

## String kernels: Summary

- A variety of principles for string kernel design have been proposed.
- Good kernel design is important for each data and each task. Performance is not the only criterion.
- Still an art, although principled ways have started to emerge.
- Fast implementation with string algorithms is often possible.
- Their application goes well beyond computational biology.

## The approach

(1) Represent explicitly each graph $\mathbf{x}$ by a vector of fixed dimension $\Phi(\mathbf{x}) \in \mathbb{R}^{p}$.

## The approach

(1) Represent explicitly each graph $\mathbf{x}$ by a vector of fixed dimension $\Phi(\mathbf{x}) \in \mathbb{R}^{p}$.
(2) Use an algorithm for regression or pattern recognition in $\mathbb{R}^{p}$.

## Example

## 2D structural keys in chemoinformatics

- Index a molecule by a binary fingerprint defined by a limited set of predefined structures

- Use a machine learning algorithm such as SVM, kNN, PLS, decision tree, etc.

## Challenge: which descriptors (patterns)?

- Expressiveness: they should retain as much information as possible from the graph
- Computation: they should be fast to compute
- Large dimension of the vector representation: memory storage, speed, statistical issues

## Indexing by substructures

- Often we believe that the presence or absence of particular substructures may be important predictive patterns
- Hence it makes sense to represent a graph by features that indicate the presence (or the number of occurrences) of these substructures
- However, detecting the presence of particular substructures may be computationally challenging...

## Subgraphs

## Definition

A subgraph of a graph $(V, E)$ is a graph $\left(V^{\prime}, E^{\prime}\right)$ with $V^{\prime} \subset V$ and $E^{\prime} \subset E$.

A graph and all its connected subgraphs.

## Indexing by all subgraphs?

## Indexing by all subgraphs?

Theorem
Computing all subgraph occurrences is NP-hard.

## Indexing by all subgraphs?

## Theorem

Computing all subgraph occurrences is NP-hard.

## Proof

- The linear graph of size $n$ is a subgraph of a graph $X$ with $n$ vertices iff $X$ has a Hamiltonian path;
- The decision problem whether a graph has a Hamiltonian path is NP-complete.

## Paths

## Definition

- A path of a graph $(V, E)$ is a sequence of distinct vertices $v_{1}, \ldots, v_{n} \in V\left(i \neq j \Longrightarrow v_{i} \neq v_{j}\right)$ such that $\left(v_{i}, v_{i+1}\right) \in E$ for $i=1, \ldots, n-1$.
- Equivalently the paths are the linear subgraphs.

## Indexing by all paths?

$$
\begin{gathered}
(0, \ldots, 0,1,0, \ldots, 0,1,0, \ldots) \\
(A) \rightarrow(A)
\end{gathered}
$$

## Indexing by all paths?

Theorem
Computing all path occurrences is NP-hard.

## Indexing by all paths?

Theorem
Computing all path occurrences is NP-hard.

## Proof

Same as for subgraphs.

## Indexing by what?

## Substructure selection

We can imagine more limited sets of substructures that lead to more computationnally efficient indexing (non-exhaustive list)

- substructures selected by domain knowledge (MDL fingerprint)
- all paths up to length $k$ (Openeye fingerprint, Nicholls 2005)
- all shortest path lengths (Borgwardt and Kriegel, 2005)
- all subgraphs up to $k$ vertices (graphlet kernel, Shervashidze et al., 2009)
- all frequent subgraphs in the database (Helma et al., 2004)

Example: Indexing by all shortest path lengths and their endpoint labels

Example: Indexing by all shortest path lengths and their endpoint labels

## Properties (Borgwardt and Kriegel, 2005)

- There are $O\left(n^{2}\right)$ shortest paths.
- The vector of counts can be computed in $O\left(n^{3}\right)$ with the Floyd-Warshall algorithm.

## Example: Indexing by all subgraphs up to $k$ vertices

## Example: Indexing by all subgraphs up to $k$ vertices

## Properties (Shervashidze et al., 2009)

- Naive enumeration scales as $O\left(n^{k}\right)$.
- Enumeration of connected graphlets in $O\left(n d^{k-1}\right)$ for graphs with degree $\leq d$ and $k \leq 5$.
- Randomly sample subgraphs if enumeration is infeasible.

## Summary

- Explicit computation of substructure occurrences can be computationnally prohibitive (subgraphs, paths);
- Several ideas to reduce the set of substructures considered;
- In practice, NP-hardness may not be so prohibitive (e.g., graphs with small degrees), the strategy followed should depend on the data considered.

## Outline

44 The Kernel Jungle

The idea

## The idea

(1) Represent implicitly each graph $\mathbf{x}$ in $\mathcal{X}$ by a vector $\Phi(\mathbf{x}) \in \mathcal{H}$ through the kernel

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\Phi(\mathbf{x})^{\top} \Phi\left(\mathbf{x}^{\prime}\right) .
$$

## The idea

(1) Represent implicitly each graph $\mathbf{x}$ in $\mathcal{X}$ by a vector $\Phi(\mathbf{x}) \in \mathcal{H}$ through the kernel

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\Phi(\mathbf{x})^{\top} \Phi\left(\mathbf{x}^{\prime}\right) .
$$

(2) Use a kernel method for classification in $\mathcal{H}$.

## Expressiveness vs Complexity

## Definition: Complete graph kernels

A graph kernel is complete if it distinguishes non-isomorphic graphs, i.e.:

$$
\forall G_{1}, G_{2} \in \mathcal{X}, \quad d_{K}\left(G_{1}, G_{2}\right)=0 \Longrightarrow G_{1} \simeq G_{2} .
$$

Equivalently, $\Phi\left(G_{1}\right) \neq \Phi\left(G_{2}\right)$ if $G_{1}$ and $G_{2}$ are not isomorphic.

## Expressiveness vs Complexity

## Definition: Complete graph kernels

A graph kernel is complete if it distinguishes non-isomorphic graphs, i.e.:

$$
\forall G_{1}, G_{2} \in \mathcal{X}, \quad d_{K}\left(G_{1}, G_{2}\right)=0 \Longrightarrow G_{1} \simeq G_{2}
$$

Equivalently, $\Phi\left(G_{1}\right) \neq \Phi\left(G_{2}\right)$ if $G_{1}$ and $G_{2}$ are not isomorphic.

## Expressiveness vs Complexity trade-off

- If a graph kernel is not complete, then there is no hope to learn all possible functions over $\mathcal{X}$ : the kernel is not expressive enough.
- On the other hand, kernel computation must be tractable, i.e., no more than polynomial (with small degree) for practical applications.
- Can we define tractable and expressive graph kernels?

## Complexity of complete kernels

Proposition (Gärtner et al., 2003)
Computing any complete graph kernel is at least as hard as the graph isomorphism problem.

## Complexity of complete kernels

## Proposition (Gärtner et al., 2003)

Computing any complete graph kernel is at least as hard as the graph isomorphism problem.

## Proof

- For any kernel $K$ the complexity of computing $d_{K}$ is the same as the complexity of computing $K$, because:

$$
d_{K}\left(G_{1}, G_{2}\right)^{2}=K\left(G_{1}, G_{1}\right)+K\left(G_{2}, G_{2}\right)-2 K\left(G_{1}, G_{2}\right) .
$$

- If K is a complete graph kernel, then computing $d_{K}$ solves the graph isomorphism problem $\left(d_{K}\left(G_{1}, G_{2}\right)=0\right.$ iff $\left.G_{1} \simeq G_{2}\right)$.

## Subgraph kernel

## Definition

- Let $\left(\lambda_{G}\right)_{G \in \mathcal{X}}$ be a set or nonnegative real-valued weights
- For any graph $G \in \mathcal{X}$ and any connected graph $H \in \mathcal{X}$, let

$$
\Phi_{H}(G)=\mid\left\{G^{\prime} \text { is a subgraph of } G: G^{\prime} \simeq H\right\} \mid .
$$

- The subgraph kernel between any two graphs $G_{1}$ and $G_{2} \in \mathcal{X}$ is defined by:

$$
K_{\text {subgraph }}\left(G_{1}, G_{2}\right)=\sum_{\substack{H \in \mathcal{X} \\ H \text { connected }}} \lambda_{H} \Phi_{H}\left(G_{1}\right) \Phi_{H}\left(G_{2}\right)
$$

## Subgraph kernel complexity

Proposition (Gärtner et al., 2003)
Computing the subgraph kernel is NP-hard.

## Subgraph kernel complexity

## Proposition (Gärtner et al., 2003)

Computing the subgraph kernel is NP-hard.

## Proof (1/2)

- Let $P_{n}$ be the path graph with $n$ vertices.
- Subgraphs of $P_{n}$ are path graphs:

$$
\Phi\left(P_{n}\right)=n e_{P_{1}}+(n-1) e_{P_{2}}+\ldots+e_{P_{n}} .
$$

- The vectors $\Phi\left(P_{1}\right), \ldots, \Phi\left(P_{n}\right)$ are linearly independent, therefore:

$$
e_{P_{n}}=\sum_{i=1}^{n} \alpha_{i} \Phi\left(P_{i}\right)
$$

where the coefficients $\alpha_{i}$ can be found in polynomial time (solving an $n \times n$ triangular system).

## Subgraph kernel complexity

## Proposition (Gärtner et al., 2003)

Computing the subgraph kernel is NP-hard.

## Proof (2/2)

- If $G$ is a graph with $n$ vertices, then it has a path that visits each node exactly once (Hamiltonian path) if and only if $\Phi(G)^{\top} e_{P_{n}}>0$, i.e.,

$$
\Phi(G)^{\top}\left(\sum_{i=1}^{n} \alpha_{i} \Phi\left(P_{i}\right)\right)=\sum_{i=1}^{n} \alpha_{i} K_{\text {subgraph }}\left(G, P_{i}\right)>0 .
$$

- The decision problem whether a graph has a Hamiltonian path is NP-complete.

## Path kernel

## Definition

The path kernel is the subgraph kernel restricted to paths, i.e.,

$$
K_{\text {path }}\left(G_{1}, G_{2}\right)=\sum_{H \in \mathcal{P}} \lambda_{H} \Phi_{H}\left(G_{1}\right) \Phi_{H}\left(G_{2}\right)
$$

where $\mathcal{P} \subset \mathcal{X}$ is the set of path graphs.

## Path kernel

## Definition

The path kernel is the subgraph kernel restricted to paths, i.e.,

$$
K_{\text {path }}\left(G_{1}, G_{2}\right)=\sum_{H \in \mathcal{P}} \lambda_{H} \Phi_{H}\left(G_{1}\right) \Phi_{H}\left(G_{2}\right)
$$

where $\mathcal{P} \subset \mathcal{X}$ is the set of path graphs.

## Proposition (Gärtner et al., 2003)

Computing the path kernel is NP-hard.

## Summary

## Expressiveness vs Complexity trade-off

- It is intractable to compute complete graph kernels.
- It is intractable to compute the subgraph kernels.
- Restricting subgraphs to be linear does not help: it is also intractable to compute the path kernel.
- One approach to define polynomial time computable graph kernels is to have the feature space be made up of graphs homomorphic to subgraphs, e.g., to consider walks instead of paths.

## Outline

## Walks

## Definition

- A walk of a graph $(V, E)$ is sequence of $v_{1}, \ldots, v_{n} \in V$ such that $\left(v_{i}, v_{i+1}\right) \in E$ for $i=1, \ldots, n-1$.
- We note $\mathcal{W}_{n}(G)$ the set of walks with $n$ vertices of the graph $G$, and $\mathcal{W}(G)$ the set of all walks.

Walks $\neq$ paths

## Walk kernel

## Definition

- Let $\mathcal{S}_{n}$ denote the set of all possible label sequences of walks of length $n$ (including vertex and edge labels), and $\mathcal{S}=\cup_{n \geq 1} \mathcal{S}_{n}$.
- For any graph $\mathcal{X}$ let a weight $\lambda_{G}(w)$ be associated to each walk $w \in \mathcal{W}(G)$.
- Let the feature vector $\Phi(G)=\left(\Phi_{s}(G)\right)_{s \in \mathcal{S}}$ be defined by:

$$
\Phi_{s}(G)=\sum_{w \in \mathcal{W}(G)} \lambda_{G}(w) \mathbf{1}(s \text { is the label sequence of } w) .
$$

## Walk kernel

## Definition

- Let $\mathcal{S}_{n}$ denote the set of all possible label sequences of walks of length $n$ (including vertex and edge labels), and $\mathcal{S}=\cup_{n \geq 1} \mathcal{S}_{n}$.
- For any graph $\mathcal{X}$ let a weight $\lambda_{G}(w)$ be associated to each walk $w \in \mathcal{W}(G)$.

$$
\Phi_{s}(G)=\sum_{w \in \mathcal{W}(G)} \lambda_{G}(w) \mathbf{1}(s \text { is the label sequence of } w) .
$$

- A walk kernel is a graph kernel defined by:

$$
K_{\text {walk }}\left(G_{1}, G_{2}\right)=\sum_{s \in \mathcal{S}} \Phi_{s}\left(G_{1}\right) \Phi_{s}\left(G_{2}\right)
$$

## Walk kernel examples

## Examples

- The $n$ th-order walk kernel is the walk kernel with $\lambda_{G}(w)=1$ if the length of $w$ is $n, 0$ otherwise. It compares two graphs through their common walks of length $n$.

## Walk kernel examples

## Examples

- The $n$ th-order walk kernel is the walk kernel with $\lambda_{G}(w)=1$ if the length of $w$ is $n, 0$ otherwise. It compares two graphs through their common walks of length $n$.
- The random walk kernel is obtained with $\lambda_{G}(w)=P_{G}(w)$, where $P_{G}$ is a Markov random walk on $G$. In that case we have:

$$
K\left(G_{1}, G_{2}\right)=P\left(\operatorname{label}\left(W_{1}\right)=\operatorname{label}\left(W_{2}\right)\right),
$$

where $W_{1}$ and $W_{2}$ are two independent random walks on $G_{1}$ and $G_{2}$, respectively (Kashima et al., 2003).

## Walk kernel examples

## Examples

- The $n$ th-order walk kernel is the walk kernel with $\lambda_{G}(w)=1$ if the length of $w$ is $n, 0$ otherwise. It compares two graphs through their common walks of length $n$.
- The random walk kernel is obtained with $\lambda_{G}(w)=P_{G}(w)$, where $P_{G}$ is a Markov random walk on $G$. In that case we have:

$$
K\left(G_{1}, G_{2}\right)=P\left(\operatorname{label}\left(W_{1}\right)=\operatorname{label}\left(W_{2}\right)\right),
$$

where $W_{1}$ and $W_{2}$ are two independent random walks on $G_{1}$ and $G_{2}$, respectively (Kashima et al., 2003).

- The geometric walk kernel is obtained (when it converges) with $\lambda_{G}(w)=\beta^{\operatorname{length}(w)}$, for $\beta>0$. In that case the feature space is of infinite dimension (Gärtner et al., 2003).

## Computation of walk kernels

## Proposition

These three kernels ( $n$ th-order, random and geometric walk kernels) can be computed efficiently in polynomial time.

## Product graph

## Definition

Let $G_{1}=\left(V_{1}, E_{1}\right)$ and $G_{2}=\left(V_{2}, E_{2}\right)$ be two graphs with labeled vertices. The product graph $G=G_{1} \times G_{2}$ is the graph $G=(V, E)$ with:
(1) $V=\left\{\left(v_{1}, v_{2}\right) \in V_{1} \times V_{2}: v_{1}\right.$ and $v_{2}$ have the same label $\}$,
(2) $E=\left\{\left(\left(v_{1}, v_{2}\right),\left(v_{1}^{\prime}, v_{2}^{\prime}\right)\right) \in V \times V:\left(v_{1}, v_{1}^{\prime}\right) \in E_{1}\right.$ and $\left.\left(v_{2}, v_{2}^{\prime}\right) \in E_{2}\right\}$.

G1

G2

G1 $\times$ G2

## Walk kernel and product graph

## Lemma

There is a bijection between:
(1) The pairs of walks $w_{1} \in \mathcal{W}_{n}\left(G_{1}\right)$ and $w_{2} \in \mathcal{W}_{n}\left(G_{2}\right)$ with the same label sequences,
(2) The walks on the product graph $w \in \mathcal{W}_{n}\left(G_{1} \times G_{2}\right)$.

## Walk kernel and product graph

## Lemma

There is a bijection between:
(1) The pairs of walks $w_{1} \in \mathcal{W}_{n}\left(G_{1}\right)$ and $w_{2} \in \mathcal{W}_{n}\left(G_{2}\right)$ with the same label sequences,
(2) The walks on the product graph $w \in \mathcal{W}_{n}\left(G_{1} \times G_{2}\right)$.

## Corollary

$$
\begin{aligned}
K_{\text {walk }}\left(G_{1}, G_{2}\right) & =\sum_{s \in \mathcal{S}} \Phi_{s}\left(G_{1}\right) \Phi_{s}\left(G_{2}\right) \\
& =\sum_{\left(w_{1}, w_{2}\right) \in \mathcal{W}\left(G_{1}\right) \times \mathcal{W}\left(G_{1}\right)} \lambda_{G_{1}}\left(w_{1}\right) \lambda_{G_{2}}\left(w_{2}\right) \mathbf{1}\left(\prime\left(w_{1}\right)=I\left(w_{2}\right)\right) \\
& =\sum_{w \in \mathcal{W}\left(G_{1} \times G_{2}\right)} \lambda_{G_{1} \times G_{2}}(w) .
\end{aligned}
$$

## Computation of the $n$ th-order walk kernel

- For the $n$ th-order walk kernel we have $\lambda_{G_{1} \times G_{2}}(w)=1$ if the length of $w$ is $n, 0$ otherwise.
- Therefore:

$$
K_{\text {nth-order }}\left(G_{1}, G_{2}\right)=\sum_{w \in \mathcal{W}_{n}\left(G_{1} \times G_{2}\right)} 1
$$

- Let $A$ be the adjacency matrix of $G_{1} \times G_{2}$. Then we get:

$$
K_{n t h-o r d e r}\left(G_{1}, G_{2}\right)=\sum_{i, j}\left[A^{n}\right]_{i, j}=1^{\top} A^{n} 1
$$

- Computation in $O\left(n\left|V_{1}\right|\left|V_{2}\right| d_{1} d_{2}\right)$, where $d_{i}$ is the maximum degree of $G_{i}$.

## Computation of random and geometric walk kernels

- In both cases $\lambda_{G}(w)$ for a walk $w=v_{1} \ldots v_{n}$ can be decomposed as:

$$
\lambda_{G}\left(v_{1} \ldots v_{n}\right)=\lambda^{i}\left(v_{1}\right) \prod_{i=2}^{n} \lambda^{t}\left(v_{i-1}, v_{i}\right)
$$

- Let $\Lambda_{i}$ be the vector of $\lambda^{i}(v)$ and $\Lambda_{t}$ be the matrix of $\lambda^{t}\left(v, v^{\prime}\right)$ :

$$
\begin{aligned}
K_{\text {walk }}\left(G_{1}, G_{2}\right) & =\sum_{n=1}^{\infty} \sum_{w \in \mathcal{W}_{n}\left(G_{1} \times G_{2}\right)} \lambda^{i}\left(v_{1}\right) \prod_{i=2}^{n} \lambda^{t}\left(v_{i-1}, v_{i}\right) \\
& =\sum_{n=0}^{\infty} \Lambda_{i} \Lambda_{t}^{n} \mathbf{1} \\
& =\Lambda_{i}\left(I-\Lambda_{t}\right)^{-1} 1
\end{aligned}
$$

- Computation in $O\left(\left|V_{1}\right|^{3}\left|V_{2}\right|^{3}\right)$.

## Extensions 1: Label enrichment

Atom relabeling with the Morgan index (Mahé et al., 2004)

Order 1 indices

- Compromise between fingerprints and structural keys.
- Other relabeling schemes are possible.
- Faster computation with more labels (less matches implies a smaller product graph).

## Extension 2: Non-tottering walk kernel

## Tottering walks

A tottering walk is a walk $w=v_{1} \ldots v_{n}$ with $v_{i}=v_{i+2}$ for some $i$.

- Tottering walks seem irrelevant for many applications.
- Focusing on non-tottering walks is a way to get closer to the path kernel (e.g., equivalent on trees).

Computation of the non-tottering walk kernel (Mahé et al., 2005)

- Second-order Markov random walk to prevent tottering walks
- Written as a first-order Markov random walk on an augmented graph
- Normal walk kernel on the augmented graph (which is always a directed graph).

## Extension 3: Subtree kernels

Remark: Here and in subsequent slides by subtree we mean a tree-like pattern with potentially repeated nodes and edges.

## Example: Tree-like fragments of molecules

## Computation of the subtree kernel (Ramon and Gärtner, 2003; Mahé and Vert, 2009)

- Like the walk kernel, amounts to computing the (weighted) number of subtrees in the product graph.
- Recursion: if $\mathcal{T}(v, n)$ denotes the weighted number of subtrees of depth $n$ rooted at the vertex $v$, then:

$$
\mathcal{T}(v, n+1)=\sum_{R \subset \mathcal{N}(v)} \prod_{v^{\prime} \in R} \lambda_{t}\left(v, v^{\prime}\right) \mathcal{T}\left(v^{\prime}, n\right),
$$

where $\mathcal{N}(v)$ is the set of neighbors of $v$.

- Can be combined with the non-tottering graph transformation as preprocessing to obtain the non-tottering subtree kernel.

## Back to label enrichment

## Link between the Morgan index and subtrees

Recall the Morgan index:

The Morgan index of order $k$ at a node $v$ in fact corresponds to the number of leaves in the $k$-th order full subtree pattern rooted at $v$.

A full subtree pattern of order 2 rooted at node 1 .

## Label enrichment via the Weisfeiler-Lehman algorithm

A slightly more involved label enrichment strategy (Weisfeiler and Lehman, 1968) is exploited in the definition and computation of the Weisfeiler-Lehman subtree kernel (Shervashidze and Borgwardt, 2009).
(1) Multiset-label determination and sorting

(2) Label compression

(3) Relabeling

## Label enrichment via the Weisfeiler-Lehman algorithm

A slightly more involved label enrichment strategy (Weisfeiler and Lehman, 1968) is exploited in the definition and computation of the Weisfeiler-Lehman subtree kernel (Shervashidze and Borgwardt, 2009).
(1) Multiset-label determination and sorting

(2) Label compression

(3) Relabeling

Compressed labels represent full subtree patterns.

## Weisfeiler-Lehman (WL) subtree kernel

$$
\begin{aligned}
& \varphi_{\text {WLsubtree }}^{(1)}(\mathrm{G})=\begin{array}{r}
(2,1,1,1,1,2,0,1,0,1,1,0,1) \\
\text { a b c d e f g h i j k } \mathrm{j}
\end{array}
\end{aligned}
$$

> Counts of Counts of original compressed node labels node labels

## Properties

- The WL features up to the $k$-th order are computed in $O(|E| k)$.
- Similarly to the Morgan index, the WL relabeling can be exploited in combination with any graph kernel (that takes into account categorical node labels) to make it more expressive (Shervashidze et al., 2011).

## Image classification (Harchaoui and Bach, 2007)

## COREL14 dataset

- 1400 natural images in 14 classes
- Compare kernel between histograms (H), walk kernel (W), subtree kernel (TW), weighted subtree kernel (wTW), and a combination (M).

## Summary: graph kernels

## What we saw

- Kernels do not allow to overcome the NP-hardness of subgraph patterns.
- They allow to work with approximate subgraphs (walks, subtrees) in infinite dimension, thanks to the kernel trick.
- However: using kernels makes it difficult to come back to patterns after the learning stage.

## Graphs

## Motivation

Data often come in the form of nodes in a graph for different reasons:

- by definition (interaction network, internet...)
- by discretization/sampling of a continuous domain
- by convenience (e.g., if only a similarity function is available)

## Example: web

## Example: social network

## Example: protein-protein interaction

## Kernel on a graph

- We need a kernel $K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)$ between nodes of the graph.
- Example: predict protein functions from high-throughput protein-protein interaction data.

## General remarks

Strategies to design a kernel on a graph

- $\mathcal{X}$ being finite, any symmetric semi-definite matrix $K$ defines a valid p.d. kernel on $\mathcal{X}$.

## General remarks

## Strategies to design a kernel on a graph

- $\mathcal{X}$ being finite, any symmetric semi-definite matrix $K$ defines a valid p.d. kernel on $\mathcal{X}$.
- How to "translate" the graph topology into the kernel?
- Direct geometric approach: $K_{i, j}$ should be "large" when $\mathbf{x}_{i}$ and $\mathbf{x}_{j}$ are "close" to each other on the graph?
- Functional approach: $\|f\|_{K}$ should be "small" when $f$ is "smooth" on the graph?
- Link discrete/continuous: is there an equivalent to the continuous Gaussian kernel on the graph (e.g., limit by fine discretization)?

## Conditionally p.d. kernels

## Hilbert distance

- Any p.d. kernel is an inner product in a Hilbert space

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\left\langle\Phi(\mathbf{x}), \Phi\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}} .
$$

- It defines a Hilbert distance:

$$
d_{K}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)^{2}=K(\mathbf{x}, \mathbf{x})+K\left(\mathbf{x}^{\prime}, \mathbf{x}^{\prime}\right)-2 K\left(\mathbf{x}, \mathbf{x}^{\prime}\right) .
$$

- $-d_{K}^{2}$ is conditionally positive definite (c.p.d.), i.e.:

$$
\forall t>0, \quad \exp \left(-t d_{K}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)^{2}\right) \text { is p.d. }
$$

## Example

## A direct approach

- For $\mathcal{X}=\mathbb{R}^{n}$, the inner product is p.d.:

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\mathbf{x}^{\top} \mathbf{x}^{\prime} .
$$

- The corresponding Hilbert distance is the Euclidean distance:

$$
d_{K}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)^{2}=\mathbf{x}^{\top} \mathbf{x}+\mathbf{x}^{\prime \top} \mathbf{x}^{\prime}-2 \mathbf{x} \top \mathbf{x}^{\prime}=\left\|\mathbf{x}-\mathbf{x}^{\prime}\right\|^{2}
$$

- $-d_{K}^{2}$ is conditionally positive definite (c.p.d.), i.e.:

$$
\forall t>0, \quad \exp \left(-t\left\|\mathbf{x}-\mathbf{x}^{\prime}\right\|^{2}\right) \text { is p.d. }
$$

## Graph distance

## Graph embedding in a Hilbert space

- Given a graph $G=(V, E)$, the graph distance $d_{G}\left(x, x^{\prime}\right)$ between any two vertices is the length of the shortest path between $x$ and $x^{\prime}$.
- We say that the graph $G=(V, E)$ can be embedded (exactly) in a Hilbert space if $-d_{G}$ is c.p.d., which implies in particular that $\exp \left(-t d_{G}\left(x, x^{\prime}\right)\right)$ is p.d. for all $t>0$.

## Graph distance

## Graph embedding in a Hilbert space

- Given a graph $G=(V, E)$, the graph distance $d_{G}\left(x, x^{\prime}\right)$ between any two vertices is the length of the shortest path between $x$ and $x^{\prime}$.
- We say that the graph $G=(V, E)$ can be embedded (exactly) in a Hilbert space if $-d_{G}$ is c.p.d., which implies in particular that $\exp \left(-t d_{G}\left(x, x^{\prime}\right)\right)$ is p.d. for all $t>0$.

## Lemma

- In general graphs cannot be embedded exactly in Hilbert spaces.
- In some cases exact embeddings exist, e.g.:
- trees can be embedded exactly,
- closed chains can be embedded exactly.

## Example: non-c.p.d. graph distance

$$
d_{G}=\left(\begin{array}{lllll}
0 & 1 & 1 & 1 & 2 \\
1 & 0 & 2 & 2 & 1 \\
1 & 2 & 0 & 2 & 1 \\
1 & 2 & 2 & 0 & 1 \\
2 & 1 & 1 & 1 & 0
\end{array}\right)
$$

$\lambda_{\text {min }}\left(\left[e^{\left(-0.2 d_{G}(i, j)\right)}\right]\right)=-0.028<0$.

## Graph distances on trees are c.p.d.

## Proof

- Let $G=(V, E)$ be a tree;
- Fix a root $x_{0} \in V$;
- Represent any vertex $x \in V$ by a vector $\Phi(x) \in \mathbb{R}^{|E|}$, where $\Phi(x)_{i}=1$ if the $i$-th edge is part of the (unique) path between $x$ and $x_{0}, 0$ otherwise.
- Then

$$
d_{G}\left(x, x^{\prime}\right)=\left\|\Phi(x)-\Phi\left(x^{\prime}\right)\right\|^{2}
$$

and therefore $-d_{G}$ is c.p.d., in particular $\exp \left(-t d_{G}\left(x, x^{\prime}\right)\right)$ is p.d. for all $t>0$.

## Example

$$
\left[e^{-d_{G}(i, j)}\right]=\left(\begin{array}{rrrrr}
1 & 0.14 & 0.37 & 0.14 & 0.05 \\
0.14 & 1 & 0.37 & 0.14 & 0.05 \\
0.37 & 0.37 & 1 & 0.37 & 0.14 \\
0.14 & 0.14 & 0.37 & 1 & 0.37 \\
0.05 & 0.05 & 0.14 & 0.37 & 1
\end{array}\right)
$$

## Graph distances on closed chains are c.p.d.

Proof: case $|V|=2 p$

- Let $G=(V, E)$ be a directed cycle with an even number of vertices $|V|=2 p$.
- Fix a root $x_{0} \in V$, number the $2 p$ edges from $x_{0}$ to $x_{0}$;
- Label the $2 p$ edges with $e_{1}, \ldots, e_{p},-e_{1}, \ldots,-e_{p}$ (vectors in $\mathbb{R}^{p}$ );
- For a vertex $v$, take $\Phi(v)$ to be the sum of the labels of the edges in the shortest directed path between $x_{0}$ and $v$.

## Another interesting graph

Cayley graph of $\mathbb{S}_{4}$

- Let $\mathbb{S}_{n}$ the set of permutations of $n$ items (symmetric group)
- Cayley graph G: connect two permutations when they differ by one adjacent transposition
- $d_{G}$ can be computed in $O(n \log n)$ how?
- $d_{G}$ is c.p.d. why?
- See Jiao and Vert (2017)

## Summary on graph distance

- Some graph distances are c.p.d, some are not
- There is a large literature in mathematics on how to "approximately" embed a graph; maybe this could be useful for machine learning?
- Graph distance is very sensitive to "noise" in edges
- We need other approaches to define a p.d. kernel that would work for all graphs, and be less sensitive to noise in the edges.

## Outline

- Applications

## Functional approach

## Motivation

- How to design a p.d. kernel on general graphs?
- Designing a kernel is equivalent to defining an RKHS.
- There are intuitive notions of smoothness on a graph.

## Idea

- Define a priori a smoothness functional on the functions $f: \mathcal{X} \rightarrow \mathbb{R}$;
- Show that it defines an RKHS and identify the corresponding kernel.

## Notations

- $\mathcal{X}=\left(\mathbf{x}_{1}, \ldots, \mathrm{x}_{m}\right)$ is finite.
- For $\mathbf{x}, \mathbf{x}^{\prime} \in \mathcal{X}$, we note $\mathbf{x} \sim \mathbf{x}^{\prime}$ to indicate the existence of an edge between $\mathbf{x}$ and $\mathbf{x}^{\prime}$
- We assume that there is no self-loop $\mathbf{x} \sim \mathbf{x}$, and that there is a single connected component.
- The adjacency matrix is $A \in \mathbb{R}^{m \times m}$ :

$$
A_{i, j}= \begin{cases}1 & \text { if } i \sim j \\ 0 & \text { otherwise }\end{cases}
$$

- $D$ is the diagonal matrix where $D_{i, i}$ is the number of neighbors of $\mathbf{x}_{i}$ $\left(D_{i, i}=\sum_{i=1}^{m} A_{i, j}\right)$.

## Example

$$
A=\left(\begin{array}{lllll}
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
1 & 1 & 0 & 1 & 0 \\
0 & 0 & 1 & 0 & 1 \\
0 & 0 & 0 & 1 & 0
\end{array}\right), \quad D=\left(\begin{array}{lllll}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 3 & 0 & 0 \\
0 & 0 & 0 & 2 & 0 \\
0 & 0 & 0 & 0 & 1
\end{array}\right)
$$

## Graph Laplacian

## Definition

The Laplacian of the graph is the matrix $L=D-A$.

$$
L=D-A=\left(\begin{array}{ccccc}
1 & 0 & -1 & 0 & 0 \\
0 & 1 & -1 & 0 & 0 \\
-1 & -1 & 3 & -1 & 0 \\
0 & 0 & -1 & 2 & -1 \\
0 & 0 & 0 & -1 & 1
\end{array}\right)
$$

## Properties of the Laplacian

## Lemma

Let $L=D-A$ be the Laplacian of a connected graph:

- For any $f: \mathcal{X} \rightarrow \mathbb{R}$,

$$
\Omega(f):=\sum_{i \sim j}\left(f\left(\mathbf{x}_{i}\right)-f\left(\mathbf{x}_{j}\right)\right)^{2}=f^{\top} L f
$$

- L is a symmetric positive semi-definite matrix
- 0 is an eigenvalue with multiplicity 1 associated to the constant eigenvector $\mathbf{1}=(1, \ldots, 1)$
- The image of $L$ is

$$
\operatorname{Im}(L)=\left\{f \in \mathbb{R}^{m}: \sum_{i=1}^{m} f_{i}=0\right\}
$$

## Proof: link between $\Omega(f)$ and $L$

$$
\begin{aligned}
\Omega(f) & =\sum_{i \sim j}\left(f\left(\mathbf{x}_{i}\right)-f\left(\mathbf{x}_{j}\right)\right)^{2} \\
& =\sum_{i \sim j}\left(f\left(\mathbf{x}_{i}\right)^{2}+f\left(\mathbf{x}_{j}\right)^{2}-2 f\left(\mathbf{x}_{i}\right) f\left(\mathbf{x}_{j}\right)\right) \\
& =\sum_{i=1}^{m} D_{i, i} f\left(\mathbf{x}_{i}\right)^{2}-2 \sum_{i \sim j} f\left(\mathbf{x}_{i}\right) f\left(\mathbf{x}_{j}\right) \\
& =f^{\top} D f-f^{\top} A f \\
& =f^{\top} L f
\end{aligned}
$$

## Proof: eigenstructure of $L$

- $L$ is symmetric because $A$ and $D$ are symmetric.
- For any $f \in \mathbb{R}^{m}, f^{\top} L f=\Omega(f) \geq 0$, therefore the (real-valued) eigenvalues of $L$ are $\geq 0: L$ is therefore positive semi-definite.
- $f$ is an eigenvector associated to eigenvalue 0 iff $f^{\top} L f=0$
iff $\sum_{i \sim j}\left(f\left(\mathbf{x}_{i}\right)-f\left(\mathbf{x}_{j}\right)\right)^{2}=0$,
iff $f\left(\mathbf{x}_{i}\right)=f\left(\mathbf{x}_{j}\right)$ when $i \sim j$,
iff $f$ is constant (because the graph is connected).
- $L$ being symmetric, $\operatorname{Im}(L)$ is the orthogonal supplement of $\operatorname{Ker}(L)$, that is, the set of functions orthogonal to $\mathbf{1}$.
$\square$

## Our first graph kernel

## Theorem

The set $\mathcal{H}=\left\{f \in \mathbb{R}^{m}: \sum_{i=1}^{m} f_{i}=0\right\}$ endowed with the norm

$$
\Omega(f)=\sum_{i \sim j}\left(f\left(\mathbf{x}_{i}\right)-f\left(\mathbf{x}_{j}\right)\right)^{2}
$$

is a RKHS whose reproducing kernel is $L^{*}$, the pseudo-inverse of the graph Laplacian.

## In case of...

## Pseudo-inverse of $L$

Remember the pseudo-inverse $L^{*}$ of $L$ is the linear application that is equal to:

- 0 on $\operatorname{Ker}(L)$
- $L^{-1}$ on $\operatorname{Im}(L)$, that is, if we write:

$$
L=\sum_{i=1}^{m} \lambda_{i} u_{i} u_{i}^{\top}
$$

the eigendecomposition of $L$ :

$$
L^{*}=\sum_{\lambda_{i} \neq 0}\left(\lambda_{i}\right)^{-1} u_{i} u_{i}^{\top}
$$

- In particular it holds that $L^{*} L=L L^{*}=\Pi_{\mathcal{H}}$, the projection onto $\operatorname{Im}(L)=\mathcal{H}$.

## Proof (1/2)

- Resticted to $\mathcal{H}$, the symmetric bilinear form:

$$
\langle f, g\rangle=f^{\top} L g
$$

is positive definite (because $L$ is positive semi-definite, and $\mathcal{H}=\operatorname{Im}(L))$. It is therefore a scalar product, making of $\mathcal{H}$ a Hilbert space (in fact Euclidean).

- The norm in this Hilbert space $\mathcal{H}$ is:

$$
\|f\|^{2}=\langle f, f\rangle=f^{\top} L f=\Omega(f)
$$

## Proof (2/2)

To check that $\mathcal{H}$ is a RKHS with reproducing kernel $K=L^{*}$, it suffices to show that:

$$
\begin{cases}\forall \mathbf{x} \in \mathcal{X}, & K_{\mathbf{x}} \in \mathcal{H} \\ \forall(\mathbf{x}, f) \in \mathcal{X} \times \mathcal{H}, & \left\langle f, K_{\mathbf{x}}\right\rangle=f(\mathbf{x})\end{cases}
$$

- $\operatorname{Ker}(K)=\operatorname{Ker}\left(L^{*}\right)=\operatorname{Ker}(L)$, implying $K \mathbf{1}=0$. Therefore, each row/column of $K$ is in $\mathcal{H}$.
- For any $f \in \mathcal{H}$, if we note $g_{i}=\langle K(i, \cdot), f\rangle$ we get:

$$
g=K L f=L^{*} L f=\Pi_{\mathcal{H}}(f)=f
$$

As a conclusion $K=L^{*}$ is the reproducing kernel of $\mathcal{H}$.

## Example

$$
L^{*}=\left(\begin{array}{rrrrr}
0.88 & -0.12 & 0.08 & -0.32 & -0.52 \\
-0.12 & 0.88 & 0.08 & -0.32 & -0.52 \\
0.08 & 0.08 & 0.28 & -0.12 & -0.32 \\
-0.32 & -0.32 & -0.12 & 0.48 & 0.28 \\
-0.52 & -0.52 & -0.32 & 0.28 & 1.08
\end{array}\right)
$$

## Interpretation of the Laplacian

$$
\begin{aligned}
\Delta f(x) & =f^{\prime \prime}(x) \\
& \sim \frac{f^{\prime}(x+d x / 2)-f^{\prime}(x-d x / 2)}{d x} \\
& \sim \frac{f(x+d x)-f(x)-f(x)+f(x-d x)}{d x^{2}} \\
& =\frac{f_{i-1}+f_{i+1}-2 f(x)}{d x^{2}} \\
& =-\frac{L f(i)}{d x^{2}}
\end{aligned}
$$

## Interpretation of regularization

For $f=[0,1] \rightarrow \mathbb{R}$ and $x_{i}=i / m$, we have:

$$
\begin{aligned}
\Omega(f) & =\sum_{i=1}^{m}\left(f\left(\frac{i+1}{m}\right)-f\left(\frac{i}{m}\right)\right)^{2} \\
& \sim \sum_{i=1}^{m}\left(\frac{1}{m} \times f^{\prime}\left(\frac{i}{m}\right)\right)^{2} \\
& =\frac{1}{m} \times \frac{1}{m} \sum_{i=1}^{m} f^{\prime}\left(\frac{i}{m}\right)^{2} \\
& \sim \frac{1}{m} \int_{0}^{1} f^{\prime}(t)^{2} d t
\end{aligned}
$$

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs
- Motivation
- Graph distance and p.d. kernels
- Construction by regularization
- The diffusion kernel
- Harmonic analysis on graphs
- Applications

## Motivation

- Consider the normalized Gaussian kernel on $\mathbb{R}^{d}$ :

$$
K_{t}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\frac{1}{(4 \pi t)^{\frac{d}{2}}} \exp \left(-\frac{\left\|\mathbf{x}-\mathbf{x}^{\prime}\right\|^{2}}{4 t}\right)
$$

- In order to transpose it to the graph, replacing the Euclidean distant by the shortest-path distance does not work.
- In this section we provide a characterization of the Gaussian kernel as the solution of a partial differential equation involving the Laplacian, which we can transpose to the graph: the diffusion equation.
- The solution of the discrete diffusion equation will be called the diffusion kernel or heat kernel.

## The diffusion equation

## Lemma

For any $\mathbf{x}_{0} \in \mathbb{R}^{d}$, the function:

$$
K_{\mathbf{x}_{0}}(\mathbf{x}, t)=K_{t}\left(\mathbf{x}_{0}, \mathbf{x}\right)=\frac{1}{(4 \pi t)^{\frac{d}{2}}} \exp \left(-\frac{\left\|\mathbf{x}-\mathbf{x}_{0}\right\|^{2}}{4 t}\right)
$$

is solution of the diffusion equation:

$$
\frac{\partial}{\partial t} K_{\mathrm{x}_{0}}(\mathbf{x}, t)=\Delta K_{\mathrm{x}_{0}}(\mathbf{x}, t)
$$

with initial condition $K_{\mathrm{x}_{0}}(\mathbf{x}, 0)=\delta_{\mathbf{x}_{0}}(\mathbf{x})$
(proof by direct computation).

## Discrete diffusion equation

For finite-dimensional $f_{t} \in \mathbb{R}^{m}$, the diffusion equation becomes:

$$
\frac{\partial}{\partial t} f_{t}=-L f_{t}
$$

which admits the following solution:

$$
f_{t}=f_{0} e^{-t L}
$$

with

$$
e^{-t L}=I-t L+\frac{t^{2}}{2!} L^{2}-\frac{t^{3}}{3!} L^{3}+\ldots
$$

## Diffusion kernel (Kondor and Lafferty, 2002)

This suggest to consider:

$$
K=e^{-t L}
$$

which is indeed symmetric positive semi-definite because if we write:

$$
L=\sum_{i=1}^{m} \lambda_{i} u_{i} u_{i}^{\top} \quad\left(\lambda_{i} \geq 0\right)
$$

we obtain:

$$
K=e^{-t L}=\sum_{i=1}^{m} e^{-t \lambda_{i}} u_{i} u_{i}^{\top}
$$

## Example: complete graph

$$
K_{i, j}= \begin{cases}\frac{1+(m-1) e^{-t m}}{} & \text { for } i=j, \\ \frac{1-e^{-t t_{m}}}{m} & \text { for } i \neq j .\end{cases}
$$

## Example: closed chain

$$
K_{i, j}=\frac{1}{m} \sum_{\nu=0}^{m-1} \exp \left[-2 t\left(1-\cos \frac{2 \pi \nu}{m}\right)\right] \cos \frac{2 \pi \nu(i-j)}{m} .
$$

## Outline

4 The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends

- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs
- Motivation
- Graph distance and p.d. kernels
- Construction by regularization
- The diffusion kernel
- Harmonic analysis on graphs
- Applications

## Motivation

- In this section we show that the diffusion and Laplace kernels can be interpreted in the frequency domain of functions
- This shows that our strategy to design kernels on graphs was based on (discrete) harmonic analysis on the graph
- This follows the approach we developed for semigroup kernels!

## Spectrum of the diffusion kernel

- Let $0=\lambda_{1}<\lambda_{2} \leq \ldots \leq \lambda_{m}$ be the eigenvalues of the Laplacian:

$$
L=\sum_{i=1}^{m} \lambda_{i} u_{i} u_{i}^{\top} \quad\left(\lambda_{i} \geq 0\right)
$$

- The diffusion kernel $K_{t}$ is an invertible matrix because its eigenvalues are strictly positive:

$$
K_{t}=\sum_{i=1}^{m} e^{-t \lambda_{i}} u_{i} u_{i}^{\top}
$$

## Norm in the diffusion RKHS

- Any function $f \in \mathbb{R}^{m}$ can be written as $f=K\left(K^{-1} f\right)$, therefore its norm in the diffusion RKHS is:

$$
\|f\|_{K_{t}}^{2}=\left(f^{\top} K^{-1}\right) K\left(K^{-1} f\right)=f^{\top} K^{-1} f .
$$

- For $i=1, \ldots, m$, let:

$$
\hat{f}_{i}=u_{i}^{\top} f
$$

be the projection of $f$ onto the eigenbasis of $K$.

- We then have:

$$
\|f\|_{K_{t}}^{2}=f^{\top} K^{-1} f=\sum_{i=1}^{m} e^{t \lambda_{i}} \hat{f}_{i}^{2}
$$

- This looks similar to $\int|\hat{f}(\omega)|^{2} e^{\sigma^{2} \omega^{2}} d \omega$...

## Discrete Fourier transform

## Definition

The vector $\hat{f}=\left(\hat{f}_{1}, \ldots, \hat{f}_{m}\right)^{\top}$ is called the discrete Fourier transform of $f \in \mathbb{R}^{n}$

- The eigenvectors of the Laplacian are the discrete equivalent to the sine/cosine Fourier basis on $\mathbb{R}^{n}$.
- The eigenvalues $\lambda_{i}$ are the equivalent to the frequencies $\omega^{2}$
- Successive eigenvectors "oscillate" increasingly as eigenvalues get more and more negative.

## Examples

## Lambda $=0$

lambda $=0$

Lambda $=6.3$

## Generalization

This observation suggests to define a whole family of kernels:

$$
K_{r}=\sum_{i=1}^{m} r\left(\lambda_{i}\right) u_{i} u_{i}^{\top}
$$

associated with the following RKHS norms:

$$
\|f\|_{K_{r}}^{2}=\sum_{i=1}^{m} \frac{\hat{f}_{i}^{2}}{r\left(\lambda_{i}\right)}
$$

where $r: \mathbb{R}^{+} \rightarrow \mathbb{R}_{*}^{+}$is a non-increasing function.

## Example : regularized Laplacian

$$
\begin{gathered}
r(\lambda)=\frac{1}{\lambda+\epsilon}, \quad \epsilon>0 \\
K=\sum_{i=1}^{m} \frac{1}{\lambda_{i}+\epsilon} u_{i} u_{i}^{\top}=(L+\epsilon l)^{-1} \\
\|f\|_{K}^{2}=f^{\top} K^{-1} f=\sum_{i \sim j}\left(f\left(\mathbf{x}_{i}\right)-f\left(\mathbf{x}_{j}\right)\right)^{2}+\epsilon \sum_{i=1}^{m} f\left(\mathbf{x}_{i}\right)^{2} .
\end{gathered}
$$

## Example

$$
(L+I)^{-1}=\left(\begin{array}{lllll}
0.60 & 0.10 & 0.19 & 0.08 & 0.04 \\
0.10 & 0.60 & 0.19 & 0.08 & 0.04 \\
0.19 & 0.19 & 0.38 & 0.15 & 0.08 \\
0.08 & 0.08 & 0.15 & 0.46 & 0.23 \\
0.04 & 0.04 & 0.08 & 0.23 & 0.62
\end{array}\right)
$$

## Outline

(4) The Kernel Jungle

- Green, Mercer, Herglotz, Bochner and friends
- Kernels for probabilistic models
- Kernels for biological sequences
- Kernels for graphs
- Kernels on graphs
- Motivation
- Graph distance and p.d. kernels
- Construction by regularization
- The diffusion kernel
- Harmonic analysis on graphs
- Applications

## Applications 1: graph partitioning

- A classical relaxation of graph partitioning is:

$$
\min _{f \in \mathbb{R}^{\mathcal{X}}} \sum_{i \sim j}\left(f_{i}-f_{j}\right)^{2} \quad \text { s.t. } \sum_{i} f_{i}^{2}=1
$$

- This can be rewritten

$$
\max _{f} \sum_{i} f_{i}^{2} \text { s.t. } \quad\|f\|_{\mathcal{H}} \leq 1
$$

- This is principal component analysis in the RKHS ("kernel PCA")

## Applications 2: search on a graph

- Let $x_{1}, \ldots, x_{q}$ be a set of $q$ nodes (the query). How to find "similar" nodes (and rank them)?
- One solution:

$$
\min _{f}\|f\|_{\mathcal{H}} \quad \text { s.t. } \quad f\left(x_{i}\right) \geq 1 \text { for } i=1, \ldots, q .
$$

## Application 3: Semi-supervised learning

## Application 3: Semi-supervised learning

Application 4: Tumor classification from microarray data (Rapaport et al., 2006)

## Data available

- Gene expression measures for more than $10 k$ genes
- Measured on less than 100 samples of two (or more) different classes (e.g., different tumors)

## Application 4: Tumor classification from microarray data

 (Rapaport et al., 2006)
## Data available

- Gene expression measures for more than 10k genes
- Measured on less than 100 samples of two (or more) different classes (e.g., different tumors)

## Goal

- Design a classifier to automatically assign a class to future samples from their expression profile
- Interpret biologically the differences between the classes

## Linear classifiers

## The approach

- Each sample is represented by a vector $x=\left(x_{1}, \ldots, x_{p}\right)$ where $p>10^{5}$ is the number of probes
- Classification: given the set of labeled sample, learn a linear decision function:

$$
f(x)=\sum_{i=1}^{p} \beta_{i} x_{i}+\beta_{0}
$$

that is positive for one class, negative for the other

- Interpretation: the weight $\beta_{i}$ quantifies the influence of gene $i$ for the classification

## Linear classifiers

## Pitfalls

- No robust estimation procedure exist for 100 samples in $10^{5}$ dimensions!
- It is necessary to reduce the complexity of the problem with prior knowledge.

## Example : Norm Constraints

## The approach

A common method in statistics to learn with few samples in high dimension is to constrain the norm of $\beta$, e.g.:

- Euclidean norm (support vector machines, ridge regression): $\|\beta\|_{2}=\sum_{i=1}^{p} \beta_{i}^{2}$
- $L_{1}$-norm (lasso regression) : $\|\beta\|_{1}=\sum_{i=1}^{p}\left|\beta_{i}\right|$

## Cons

## Pros

- Good performance in classification
- Limited interpretation (small weights)
- No prior biological knowledge

## Example 2: Feature Selection

## The approach

Constrain most weights to be 0, i.e., select a few genes ( $<20$ ) whose expression are enough for classification. Interpretation is then about the selected genes.

## Pros

- Good performance in classification
- Useful for biomarker selection
- Apparently easy interpretation

## Cons

- The gene selection process is usually not robust
- Wrong interpretation is the rule (too much correlation between genes)

## Pathway interpretation

## Motivation

- Basic biological functions are usually expressed in terms of pathways and not of single genes (metabolic, signaling, regulatory)
- Many pathways are already known
- How to use this prior knowledge to constrain the weights to have an interpretation at the level of pathways?

Solution (Rapaport et al., 2006)

- Constrain the diffusion RKHS norm of $\beta$
- Relevant if the true decision function is indeed smooth w.r.t. the biological network

## Pathway interpretation

## Bad example

- The graph is the complete known metabolic network of the budding yeast (from KEGG database)
- We project the classifier weight learned by a SVM
- Good classification accuracy, but no possible interpretation!

## Pathway interpretation

## Good example

- The graph is the complete known metabolic network of the budding yeast (from KEGG database)
- We project the classifier weight learned by a spectral SVM
- Good classification accuracy, and good interpretation!

## Part 6

## Characterizing probabilities with kernels

## Introduction

- We have seen how to represent each individual data-point by an embedding in some feature space.
- This allows to compare data points by evaluating the kernel.
- Now we are interested in comparing two or more sets of data-points, or more generally distributions of data points.

## Introduction

- We have seen how to represent each individual data-point by an embedding in some feature space.

- Now we are interested in comparing two or more sets of data-points, or more generally distributions of data points.

Disclaimer: Some of the figures and slides are borrowed from the lecture by Arthur Gretton which you can find here:
https://www.gatsby.ucl.ac.uk/~gretton/teaching.html

## Motivation I: Comparing two distributions

- Data: Samples from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: do $\mathbb{P}$ and $\mathbb{Q}$ differ?

Differences between dogs and fish.

## Motivation I: Comparing two distributions

- Data: Samples from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: do $\mathbb{P}$ and $\mathbb{Q}$ differ?

Samples from $P$

Samples from Q

## Motivation I: Comparing two distributions

- Data: Samples from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: do $\mathbb{P}$ and $\mathbb{Q}$ differ?

Difference in brain signals: Do local field potential (LFP) signals change when measured near a spike burst?

## Motivation I: Comparing two distributions

- Data: Samples from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: do $\mathbb{P}$ and $\mathbb{Q}$ differ?

Difference in brain signals: Do local field potential (LFP) signals change when measured near a spike burst?

Comparaing the means?

## Motivation II: Detecting dependence

$X_{1}$ : Honourable senators, I have a question for the Leader of the Government in the Senate with regard to the support funding to farmers that has been announced. Most farmers have not received any money yet.
$X_{2}$ : No doubt there is great pressure on provincial and municipal governments in relation to the issue of child care, but the reality is that there have been no cuts to child care funding from the federal government to the provinces. In fact, we have increased federal investments for early childhood development.
$Y_{1}$ : Honorables sénateurs, ma question s'adresse au leader du gouvernement au Sénat et concerne l'aide financiére qu'on a annoncée pour les agriculteurs. La plupart des agriculteurs n'ont encore rien reu de cet argent.
$Y_{2}$ :ll est évident que les ordres de gouvernements provinciaux et municipaux subissent de fortes pressions en ce qui concerne les ser-
 vices de garde, mais le gouvernement n'a pas réduit le financement qu'il verse aux provinces pour les services de garde. Au contraire, nous avons augmenté le financement fédéral pour le développement des jeunes enfants.

For any $f \in \mathcal{H}$ and $x \in \mathcal{X}$,

$$
f(x)=\left\langle f, K_{x}\right\rangle_{\mathcal{H}}
$$

- For any Borel measure $\mathbb{P}$ and $\mathbb{Q}$,

$$
\mathbb{E}_{(X, Y) \sim \mathbb{P}, \mathbb{Q}} K(X, Y)=\left\langle\mu_{\mathbb{P}}, \mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}}
$$

- The generalized kernel trick: For any $f \in \mathcal{H}$ and Borel measure $\mathbb{P}$,

$$
\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}
$$

## Kernel Mean Embedding

## Kernel Mean Embedding

The kernel mean embedding: $\mu_{\mathbb{P}}=\mathbb{E}_{X \sim \mathbb{P}}\left[K_{X}\right]$
The generalized kernel trick: $\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}$ for all $f \in \mathcal{H}$.

## Kernel Mean Embedding

## Kernel Mean Embedding

The kernel mean embedding: $\mu_{\mathbb{P}}=\mathbb{E}_{X \sim \mathbb{P}}\left[K_{X}\right]$
The generalized kernel trick: $\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}$ for all $f \in \mathcal{H}$.

- Mean embedding $\mu_{\mathbb{P}}$ summarizes $\mathbb{P}$ :

Can compute expectations under $\mathbb{P}$ of all functions in $\mathcal{H}$ using $\mu_{\mathbb{P}}$.

- In practice, you can estimate $\mu_{\mathbb{P}}$ using $N$ i.i.d. samples from $\mathbb{P}$ :

$$
\hat{\mu}_{\mathbb{P}}(x)=\frac{1}{N} \sum_{i=1}^{N} K\left(X_{i}, x\right), \quad X_{i} \stackrel{i . i . d .}{\sim} \mathbb{P}
$$

## Kernel Mean Embedding

## Kernel Mean Embedding

The kernel mean embedding: $\mu_{\mathbb{P}}=\mathbb{E}_{X \sim \mathbb{P}}\left[K_{X}\right]$
The generalized kernel trick: $\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}$ for all $f \in \mathcal{H}$.

- Mean embedding $\mu_{\mathbb{P}}$ summarizes $\mathbb{P}$ :

Can compute expectations under $\mathbb{P}$ of all functions in $\mathcal{H}$ using $\mu_{\mathbb{P}}$.

- In practice, you can estimate $\mu_{\mathbb{P}}$ using $N$ i.i.d. samples from $\mathbb{P}$ :

$$
\hat{\mu}_{\mathbb{P}}(x)=\frac{1}{N} \sum_{i=1}^{N} K\left(X_{i}, x\right), \quad x_{i} \stackrel{i . i . d .}{\sim} \mathbb{P}
$$

## Kernel Mean Embedding

## Kernel Mean Embedding

The kernel mean embedding: $\mu_{\mathbb{P}}=\mathbb{E}_{X \sim \mathbb{P}}\left[K_{X}\right]$
The generalized kernel trick: $\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}$ for all $f \in \mathcal{H}$.

- Mean embedding $\mu_{\mathbb{P}}$ summarizes $\mathbb{P}$ :

Can compute expectations under $\mathbb{P}$ of all functions in $\mathcal{H}$ using $\mu_{\mathbb{P}}$.

- In practice, you can estimate $\mu_{\mathbb{P}}$ using $N$ i.i.d. samples from $\mathbb{P}$ :

$$
\hat{\mu}_{\mathbb{P}}(x)=\frac{1}{N} \sum_{i=1}^{N} K\left(X_{i}, x\right), \quad X_{i} \stackrel{i . i . d .}{\sim} \mathbb{P}
$$

Does the mean embedding $\mu_{\mathbb{P}}$ exist? i.e. an element $\mu_{\mathbb{P}} \in \mathcal{H}$ such that

$$
\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}, \forall f \in \mathcal{H}
$$

## Existence of mean embeddings

## Proposition

Let $\mathbb{P}$ be a Borel probability distribution on a set $\mathcal{X}$ endowed with its Borel sigma algebra. Let $K$ be a p.d. kernel defined on $\mathcal{X}$ with corresponding RKHS $\mathcal{H}$. Assume that $\mathbb{E}_{X \sim \mathbb{P}}[\sqrt{K(X, X)}]<\infty$. Then there exits a unique element $\mu_{\mathbb{P}} \in \mathcal{H}$ such that

$$
\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}, \forall f \in \mathcal{H}
$$

In particular, for any $y \in \mathcal{X}$, it holds that:

$$
\mu_{\mathbb{P}}(y)=\left\langle K_{y}, \mu_{\mathbb{P}}\right\rangle=\mathbb{E}_{X \sim \mathbb{P}}[K(X, y)]
$$

## Existence of mean embeddings

## Proposition

Let $\mathbb{P}$ be a Borel probability distribution on a set $\mathcal{X}$ endowed with its Borel sigma algebra. Let $K$ be a p.d. kernel defined on $\mathcal{X}$ with corresponding RKHS $\mathcal{H}$. Assume that $\mathbb{E}_{X \sim \mathbb{P}}[\sqrt{K(X, X)}]<\infty$. Then there exits a unique element $\mu_{\mathbb{P}} \in \mathcal{H}$ such that

$$
\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}, \forall f \in \mathcal{H}
$$

In particular, for any $y \in \mathcal{X}$, it holds that:

$$
\mu_{\mathbb{P}}(y)=\left\langle K_{y}, \mu_{\mathbb{P}}\right\rangle=\mathbb{E}_{X \sim \mathbb{P}}[K(X, y)] .
$$

Proof:
The linear form on $\mathcal{H}: T_{\mathbb{P}} f=\mathbb{E}_{X \sim \mathbb{P}}[f(X)]$ is bounded by assumption:

$$
\left|T_{\mathbb{P}} f\right| \leq \mathbb{E}_{X \sim \mathbb{P}}[|f(X)|]=\mathbb{E}_{X \sim \mathbb{P}}\left[\left|\left\langle f, K_{X}\right\rangle_{\mathcal{H}}\right|\right] \leq \mathbb{E}_{X \sim \mathbb{P}}\left[\sqrt{K(X, X)}\|f\|_{\mathcal{H}}\right]
$$

Hence, by Riesz's theorem, there exists $\mu_{\mathbb{P}} \in \mathcal{H}$ such that $T_{\mathbb{P}} f=\left\langle f, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}$.

6 Open Problems and Research Topics

## Motivation: Comparing two distributions

- Data: Samples from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: do $\mathbb{P}$ and $\mathbb{Q}$ differ?

Differences between dogs and fish.

## The Maximum Mean Discrepancy

The maximum mean discrepancy (MMD) is the RKHS distance between mean embeddings:

$$
M M D^{2}(\mathbb{P}, \mathbb{Q})=\left\|\mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\|_{\mathcal{H}}^{2}
$$

## The Maximum Mean Discrepancy

The maximum mean discrepancy (MMD) is the RKHS distance between mean embeddings:

$$
\begin{aligned}
M M D^{2}(\mathbb{P}, \mathbb{Q}) & =\left\|\mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\|_{\mathcal{H}}^{2} \\
& =\left\langle\mu_{\mathbb{P}}, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}+\left\langle\mu_{\mathbb{Q}}, \mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}}-2\left\langle\mu_{\mathbb{P}}, \mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}}
\end{aligned}
$$

## The Maximum Mean Discrepancy

The maximum mean discrepancy (MMD) is the RKHS distance between mean embeddings:

$$
\begin{aligned}
M M D^{2}(\mathbb{P}, \mathbb{Q})= & \left\|\mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\|_{\mathcal{H}}^{2} \\
= & \left\langle\mu_{\mathbb{P}}, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}+\left\langle\mu_{\mathbb{Q}}, \mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}}-2\left\langle\mu_{\mathbb{P}}, \mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}} \\
= & \mathbb{E}_{X, X^{\prime} \sim \mathbb{P} \otimes \mathbb{P}}\left[k\left(X, X^{\prime}\right)\right]+\mathbb{E}_{Y, Y^{\prime} \sim \mathbb{Q} \otimes \mathbb{Q}}\left[k\left(Y, Y^{\prime}\right)\right] \\
& -2 \mathbb{E}_{X, Y \sim \mathbb{P} \otimes \mathbb{Q}}[k(X, Y)]
\end{aligned}
$$

## The Maximum Mean Discrepancy

The maximum mean discrepancy (MMD) is the RKHS distance between mean embeddings:

$$
\begin{aligned}
M M D^{2}(\mathbb{P}, \mathbb{Q})= & \left\|\mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\|_{\mathcal{H}}^{2} \\
= & \left\langle\mu_{\mathbb{P}}, \mu_{\mathbb{P}}\right\rangle_{\mathcal{H}}+\left\langle\mu_{\mathbb{Q}}, \mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}}-2\left\langle\mu_{\mathbb{P}}, \mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}} \\
= & \mathbb{E}_{X, X^{\prime} \sim \mathbb{P} \otimes \mathbb{P}}\left[k\left(X, X^{\prime}\right)\right]+\mathbb{E}_{Y, Y^{\prime} \sim \mathbb{Q} \otimes \mathbb{Q}}\left[k\left(Y, Y^{\prime}\right)\right] \\
& -2 \mathbb{E}_{X, Y \sim \mathbb{P} \otimes \mathbb{Q}}[k(X, Y)]
\end{aligned}
$$

- Intra-similarity terms : $\mathbb{E}_{X, X^{\prime} \sim \mathbb{P} \otimes \mathbb{P}}\left[k\left(X, X^{\prime}\right)\right]$ and $\mathbb{E}_{Y, Y^{\prime} \sim \mathbb{Q} \otimes \mathbb{Q}}\left[k\left(Y, Y^{\prime}\right)\right]$.
- Inter-similarity term: $\mathbb{E}_{X, Y \sim \mathbb{P} \otimes \mathbb{Q}}[k(X, Y)]$.
- In general, MMD is a semi-metric: $(\operatorname{MMD}(\mathbb{P}, \mathbb{Q})=0 \nRightarrow \mathbb{P}=\mathbb{Q})$.
- For some kernels (called characteristic kernels), MMD is a metric $(M M D(\mathbb{P}, \mathbb{Q})=0 \Longleftrightarrow \mathbb{P}=\mathbb{Q})$.
- From now on, we assume MMD is a metric. Later, we'll say more about characteristic kernels.

## Unbiased esitimation of the MMD

- Data: i.i.d. samples from $\mathbb{P}$ and $\mathbb{Q}$

## Unbiased esitimation of the MMD

- Data: i.i.d. samples from $\mathbb{P}$ and $\mathbb{Q}$

Biased estimate of the $M M D^{2}$ :
$\left.M \widehat{M D^{2}(\mathbb{P}}, \mathbb{Q}\right)=\frac{1}{N^{2}} \sum_{i, j} K\left(\operatorname{dog}_{i}, \operatorname{dog}_{j}\right)+\frac{1}{M^{2}} \sum_{i, j} K\left(\right.$ fish $_{i}$, fish $\left._{j}\right)$

$$
-\frac{2}{N M} \sum_{i, j} k\left(\operatorname{dog}_{i}, f i s h_{j}\right)
$$

## Unbiased esitimation of the MMD

- Data: i.i.d. samples from $\mathbb{P}$ and $\mathbb{Q}$

Unbiased estimate of the $M M D^{2}$ :
$\left.M \widehat{M D^{2}(\mathbb{P}}, \mathbb{Q}\right)=\frac{1}{N(N-1)} \sum_{i \neq j} K\left(\operatorname{dog}_{i}, \operatorname{dog}_{j}\right)+\frac{1}{M(M-1)} \sum_{i \neq j} K\left(\right.$ fish $\left._{i}, f i s h_{j}\right)$

$$
-\frac{2}{N M} \sum_{i, j} k\left(\operatorname{dog}_{i}, f i s h_{j}\right)
$$

## MMD as an Integral Probability Metric

## Integral Probability Metric

Let $\mathcal{F}$ be a set of measurable functions. An integral probability metric associated to the class $\mathcal{F}$ is a semi-metric defined as

$$
\mathcal{D}_{\mathcal{F}}(\mathbb{P}, \mathbb{Q}):=\sup _{f \in \mathcal{F}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]
$$

## MMD as an Integral Probability Metric

## Integral Probability Metric

Let $\mathcal{F}$ be a set of measurable functions. An integral probability metric associated to the class $\mathcal{F}$ is a semi-metric defined as

$$
\mathcal{D}_{\mathcal{F}}(\mathbb{P}, \mathbb{Q}):=\sup _{f \in \mathcal{F}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]
$$

- MMD obtained by choosing $\mathcal{F}=\left\{f \in \mathcal{H} \mid\|f\|_{\mathcal{H}} \leq 1\right\}$ :

$$
M M D(\mathbb{P}, \mathbb{Q}):=\sup _{\substack{f \in \mathcal{H} \\\|f\|_{\mathcal{H}} \leq 1}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]
$$

## MMD as an Integral Probability Metric

## Integral Probability Metric

Let $\mathcal{F}$ be a set of measurable functions. An integral probability metric associated to the class $\mathcal{F}$ is a semi-metric defined as

$$
\mathcal{D}_{\mathcal{F}}(\mathbb{P}, \mathbb{Q}):=\sup _{f \in \mathcal{F}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]
$$

- MMD obtained by choosing $\mathcal{F}=\left\{f \in \mathcal{H} \mid\|f\|_{\mathcal{H}} \leq 1\right\}$ :

$$
M M D(\mathbb{P}, \mathbb{Q}):=\sup _{\substack{f \in \mathcal{H} \\\|f\|_{\mathcal{H}} \leq 1}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]
$$

- Other choices for the set $\mathcal{F}$ :
- Bounded continuous $\rightarrow$ Dudley's metric.
- Bounded variations $\rightarrow$ Kolmogorov metric.
- Bounded Lipschitz $\rightarrow$ 1-Wasserstein distance.

## MMD as an Integral Probability Metric

- MMD obtained by choosing $\mathcal{F}=\left\{f \in \mathcal{H} \mid\|f\|_{\mathcal{H}} \leq 1\right\}$ :

$$
M M D(\mathbb{P}, \mathbb{Q})=\sup _{\substack{f \in \mathcal{H} \\\|f\|_{\mathcal{H}} \leq 1}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]
$$

## MMD as an Integral Probability Metric

- MMD obtained by choosing $\mathcal{F}=\left\{f \in \mathcal{H} \mid\|f\|_{\mathcal{H}} \leq 1\right\}$ :

$$
\begin{aligned}
M M D(\mathbb{P}, \mathbb{Q}) & =\sup _{\substack{f \in \mathcal{H} \\
\|f\|_{\mathcal{H}} \leq 1}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)] \\
& =\sup _{\substack{f \in \mathcal{H} \\
\|f\|_{\mathcal{H}} \leq 1}}\left\langle f, \mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}}
\end{aligned}
$$

## MMD as an Integral Probability Metric

- MMD obtained by choosing $\mathcal{F}=\left\{f \in \mathcal{H} \mid\|f\|_{\mathcal{H}} \leq 1\right\}$ :

$$
\begin{aligned}
M M D(\mathbb{P}, \mathbb{Q})= & \sup _{\substack{f \in \mathcal{H} \\
\\
\|f\|_{\mathcal{H}} \leq 1}} \mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)] \\
= & \sup _{\substack{f \in \mathcal{H}\\
} f f \|_{\mathcal{H}} \leq 1}\left\langle f, \mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}} \\
= & \left\langle f^{\star}, \mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}} \\
= & \left\|\mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\|_{\mathcal{H}}
\end{aligned}
$$

$$
f^{\star}=\frac{\mu_{\mathbb{P}}-\mu_{\mathbb{Q}}}{\left\|\mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\|}
$$

$f^{\star}$ is called the witness function

## Outline

(5) Characterizing probabilities with kernels

- Kernel mean embedding
- The Maximum Mean Discrepancy
- Applications (I): Statistical testing using the MMD
- Applications (II): Learning generative models
- Characteristic kernels

## A statistical test using MMD

- Data: Samples $x_{1}, \ldots, x_{N}$ and $y_{1}, \ldots, y_{N}$ from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: Is $\mathbb{P}=\mathbb{Q}$ ?

## A statistical test using MMD

- Data: Samples $x_{1}, \ldots, x_{N}$ and $y_{1}, \ldots, y_{N}$ from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: Is $\mathbb{P}=\mathbb{Q}$ ?

Empirial estimate of the MMD:

$$
\begin{array}{rl}
M M D^{2}(\mathbb{P}, \mathbb{Q})=\frac{1}{N(N-1)} \sum_{i \neq j} & K\left(x_{i}, x_{j}\right)+\frac{1}{N(N-1)} \sum_{i \neq j} K\left(y_{i}, y_{j}\right) \\
& -\frac{2}{N^{2}} \sum_{i, j} K\left(x_{i}, y_{j}\right)
\end{array}
$$

## A statistical test using MMD

- Data: Samples $x_{1}, \ldots, x_{N}$ and $y_{1}, \ldots, y_{N}$ from unknown distributions $\mathbb{P}$ and $\mathbb{Q}$.
- Goal: Is $\mathbb{P}=\mathbb{Q}$ ?

Empirial estimate of the MMD:

$$
\begin{gathered}
\left.M M \widehat{D^{2}(\mathbb{P}}, \mathbb{Q}\right)=\frac{1}{N(N-1)} \sum_{i \neq j} K\left(x_{i}, x_{j}\right)+\frac{1}{N(N-1)} \sum_{i \neq j} K\left(y_{i}, y_{j}\right) \\
-\frac{2}{N^{2}} \sum_{i, j} K\left(x_{i}, y_{j}\right)
\end{gathered}
$$

- Null hypothesis $h_{0}$ when $\mathbb{P}=\mathbb{Q}$.
$M M D^{2}(\mathbb{P}, \mathbb{Q})$ should be close to zero.
- Alternative hypothesis $h_{1}$ when $\mathbb{P} \neq \mathbb{Q}$.
$M M{ }^{2}(\mathbb{P}, \mathbb{Q})$ should be far away from zero.
- What do close or far away mean here?

## Behaviour of MMD when $\mathbb{P} \neq \mathbb{Q}$

## Behaviour of MMD when $\mathbb{P} \neq \mathbb{Q}$

The statistic $\left.M \widehat{M D^{2}(\mathbb{P}}, \mathbb{Q}\right)$ is asymptotically normal [Gretton, 2006]:

$$
\frac{\left.\sqrt{n}\left(M M \widehat{M D^{2}(\mathbb{P}}, \mathbb{Q}\right)-M M D^{2}(\mathbb{P}, \mathbb{Q})\right)}{\sqrt{V(\mathbb{P}, \mathbb{Q})}} \rightarrow \mathcal{N}(0,1)
$$

where $V(\mathbb{P}, \mathbb{Q})$ is the asymptotic variance of $\sqrt{n} \times\left(M M^{2}(\mathbb{P}, \mathbb{Q})\right)$.

## Behaviour of MMD when $\mathbb{P}=\mathbb{Q}$

## Behaviour of MMD when $\mathbb{P}=\mathbb{Q}$

## Behaviour of MMD when $\mathbb{P}=\mathbb{Q}$

- $z_{i}$ are i.i.d. standard gaussians: $z_{i} \sim \mathcal{N}(0,1)$
- $\lambda_{i}$ are eigenvalues of the operator $f \mapsto \mathbb{E}_{X \sim \mathbb{P}}\left[\tilde{K}\left(X, X^{\prime}\right) f(X)\right]$
- $\tilde{K}$ the centered kernel:

$$
\tilde{K}\left(x, x^{\prime}\right)=\left\langle K(x, .)-\mu_{\mathbb{P}}, K\left(x^{\prime}, .\right)-\mu_{\mathbb{P}}\right\rangle_{\mathcal{H}} .
$$

## A statistical test using MMD

$$
\left.T_{0}:=n M M \widehat{D^{2}(\mathbb{P}}, \mathbb{Q}\right) \approx \begin{cases}n M M D^{2}(\mathbb{P}, \mathbb{Q})+\sqrt{n} \mathcal{N}(0, V(\mathbb{P}, \mathbb{Q})), & \mathbb{P} \neq \mathbb{Q} \\ 2 \sum_{i=1}^{\infty} \lambda_{i}\left(z_{i}^{2}-1\right), & \mathbb{P}=\mathbb{Q}\end{cases}
$$

## A statistical test using MMD

- Fix a significance level $\alpha$ and quantile $c_{\alpha}$ s.t. $\mathbb{P}\left(T_{0}>c_{\alpha} \mid h_{0}\right)=\alpha$.
- If $T_{0} \geq c_{\alpha}$, reject the null, i.e. $(\mathbb{P}=\mathbb{Q}$ unlikely)
- Otherwise, cannot reject ( $\mathbb{P}=\mathbb{Q}$ is likely).

$$
\left.T_{0}:=n M M \widehat{D^{2}(\mathbb{P}}, \mathbb{Q}\right) \approx \begin{cases}n M M D^{2}(\mathbb{P}, \mathbb{Q})+\sqrt{n} \mathcal{N}(0, V(\mathbb{P}, \mathbb{Q})), & \mathbb{P} \neq \mathbb{Q} \\ 2 \sum_{i=1}^{\infty} \lambda_{i}\left(z_{i}^{2}-1\right), & \mathbb{P}=\mathbb{Q}\end{cases}
$$

## A statistical test using MMD

- Fix a significance level $\alpha$ and quantile $c_{\alpha}$ s.t. $\mathbb{P}\left(T_{0}>c_{\alpha} \mid h_{0}\right)=\alpha$.
- If $T_{0} \geq c_{\alpha}$, reject the null, i.e. ( $\mathbb{P}=\mathbb{Q}$ unlikely)
- Otherwise, cannot reject ( $\mathbb{P}=\mathbb{Q}$ is likely).

How can we tell if $T_{0}:=n M_{M}^{2}(\mathbb{P}, \mathbb{Q}) \geq c_{\alpha}$ ?

- Let $T$ be a r.v. under the null distribution: $T \sim 2 \sum_{i=1}^{\infty} \lambda_{i}\left(z_{i}^{2}-1\right)$.
- If the $p$-value $p:=\mathbb{P}_{T}\left(T>T_{0}\right) \leq \alpha$, then $T_{0} \geq c_{\alpha}$.
- For $T_{1}, \ldots, T_{J}$ samples from the null: $p \approx\left|\left\{j \mid T_{j} \geq T_{0}\right\}\right| / J$.

Can use a permutation test to construct $T_{1}, \ldots, T_{J}$.

## A statistical test using MMD

Original empirical MMD for dogs and fish:

$$
\begin{aligned}
X= & {\left[\begin{array}{ll} 
& \\
Y= & {\left[\begin{array}{l}
\text { nnd }
\end{array}\right]} \\
\widehat{M M D}^{2}= & \frac{1}{n(n-1)} \sum_{i \neq j} k\left(x_{i}, x_{j}\right) \\
& +\frac{1}{n(n-1)} \sum_{i \neq j} k\left(\mathrm{y}_{i}, \mathrm{y}_{j}\right) \\
& -\frac{2}{n^{2}} \sum_{i, j} k\left(x_{i}, \mathrm{y}_{j}\right)
\end{array}\right.}
\end{aligned}
$$

For each permutation $j$ set $T_{j}=n M M D^{2}(\tilde{\mathbb{P}}, \tilde{\mathbb{Q}})$

## A statistical test using MMD

Permuted dog and fish samples (merdogs):

$$
\begin{aligned}
\tilde{X}= & {\left[\begin{array}{ll}
\tilde{Y}= & {\left[\begin{array}{l} 
\\
\widehat{M M D}^{2}
\end{array}=\frac{1}{n(n-1)} \sum_{i \neq j} k\left(\tilde{x}_{i}, \tilde{x}_{j}\right)\right.} \\
& +\frac{1}{n(n-1)} \sum_{i \neq j} k\left(\tilde{\mathrm{y}}_{i}, \tilde{\mathrm{y}}_{j}\right) \\
& -\frac{2}{n^{2}} \sum_{i, j} k\left(\tilde{x}_{i}, \tilde{y}_{j}\right)
\end{array}\right.}
\end{aligned}
$$

Permutation simulates
$P=Q$

For each permutation $j$ set $T_{j}=n M M D^{2}(\tilde{\mathbb{P}}, \tilde{\mathbb{Q}})$

## A statistical test using MMD

- Fix a significance level $\alpha$ (usually a small value: 0.05.)
- If $T_{0} \geq c_{\alpha}$, reject the null, i.e. ( $\mathbb{P}=\mathbb{Q}$ unlikely)
- Otherwise, cannot reject ( $\mathbb{P}=\mathbb{Q}$ is likely).

How can we tell if $T_{0}:=n M_{M}^{2}(\mathbb{P}, \mathbb{Q}) \geq c_{\alpha}$ ?

- Let $T$ be a r.v. under the null distribution: $T \sim 2 \sum_{i=1}^{\infty} \lambda_{i}\left(z_{i}^{2}-1\right)$.
- If the $p$-value $p:=\mathbb{P}_{T}\left(T>T_{0}\right) \leq \alpha$, then $T_{0} \geq c_{\alpha}$.
- For $T_{1}, \ldots, T_{J}$ samples from the null: $p \approx\left|\left\{j \mid T_{j} \geq T_{0}\right\}\right| / J$.

Can use a permutation test to construct $T_{1}, \ldots, T_{J}$.

## Adversarial training [Goodfellow 2014]

Divergence $D(\mathbb{P}, \mathbb{Q})$ defined by maximizing a variational objective $\mathcal{G}$ :

$$
D(\mathbb{P}, \mathbb{Q}):=\sup _{f \in \mathcal{F}} \mathcal{G}(f, \mathbb{P}, \mathbb{Q})
$$

- Critic: maximizes $\mathcal{G}(f, \mathbb{P}, \mathbb{Q})$ over $f \in \mathcal{F}$ to find optimal critic $f^{\star}$.
- Generator: minimizes $\mathcal{D}(\mathbb{P}, \mathbb{Q})=\mathcal{G}\left(f^{\star}, \mathbb{P}, \mathbb{Q}\right)$ over $\mathbb{Q}$.
- Recover the MMD when $\mathcal{F}$ is the unit ball in an RKHS $\mathcal{H}$.

## Learning generative models using MMD

Goal is to solve the optimization problem:

$$
\min _{\theta} M M D^{2}\left(\mathbb{P}, \mathbb{Q}_{\theta}\right)
$$

## Learning generative models using MMD

Goal is to solve the optimization problem:

$$
\min _{\theta} M M D^{2}\left(\mathbb{P}, \mathbb{Q}_{\theta}\right)
$$

(1) Sample a mini-batch of i.i.d samples $X_{1}, \ldots, X_{B} \sim \mathbb{P}$ from data-set.
(2) Sample a mini-batch of i.i.d. latent noise $Z_{1}, \ldots, Z_{B} \sim \mu$.
(3) Generate IGM samples $Y_{b}=G_{\theta}\left(Z_{b}\right) \sim \mathbb{Q}_{\theta}$ for $1 \leq b \leq B$.
(9) Compute empirical loss $\hat{\mathcal{L}}(\theta):=\widehat{M M D^{2}}\left(\mathbb{P}, \mathbb{Q}_{\theta}\right)$. (Differentiable in $\theta$ )
(6) Update parameters of the model using SGD:

$$
\theta \leftarrow \theta-\gamma \nabla \hat{\mathcal{L}}(\theta)
$$

## Learning generative models using MMD

IGM trained using an RBF kernel on MNIST dataset.

Need better image features.

- In practice, choice of the kernel is crucial for good performance.
- Hard to design a kernel for high dimensional data like images.
- Why not learning it?

## Learning generative models using MMD

Goal is to solve the optimization problem:

$$
\min _{\theta} \sup _{k \in \mathcal{K}} M M D_{k}^{2}\left(\mathbb{P}, \mathbb{Q}_{\theta}\right)
$$

- $\mathcal{K}$ is a family of kernels,
- ex: parmaterized by a neural network:

$$
k(x, y)=h(\varphi(x), \varphi(y))
$$

where $\varphi$ is a NN and $h$ is a fixed p.d. kernel.

- Adaptively select an MMD that best discriminates between $\mathbb{P}$ and current model $\mathbb{Q}$.
- In practice, alternate between gradient steps on $k$ and on $\theta$ :
(Adversarial training).

## Learning generative models using MMD

IGM trained on MNIST dataset.

Samples are better!

## Learning generative models using MMD

IGM trained on CelebA dataset.

[A., Sutherland, Binkowski and Gretton, 2018]

## Learning generative models using MMD

IGM trained on CelebA dataset.

[A., Sutherland, Binkowski and Gretton, 2018]

- More to the story: regularization, stability in optimization, evaluation, etc

## Summary

- It is possible to represent probability distributions using kernels through the concept of mean embeddings.
- The maximum mean discrepancy (MMD), allows to compare probabilities by comparing their mean embeddings.
- MMD can be used for various applications:
- Two sample tests
- Learning implicit generative models (like GANs)
- Other applications include
- Dependence detection
- Feature selection
- Bling source separaion (e.g. ICA)
- Often assume good kernels which do not discard information about distributions: characteristic kernels.

## Can mean embeddings characterize probabilities?

Question: Given two probability distributions $\mathbb{P}$ and $\mathbb{Q}$ with mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$, can we confidently tell if $\mathbb{P}$ and $\mathbb{Q}$ are different or not based only on the summary given by $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ ?

## Can mean embeddings characterize probabilities?

Question: Given two probability distributions $\mathbb{P}$ and $\mathbb{Q}$ with mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$, can we confidently tell if $\mathbb{P}$ and $\mathbb{Q}$ are different or not based only on the summary given by $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ ?
Example 1: Linear kernel $K\left(x, x^{\prime}\right)=x^{\top} x^{\prime}$.

## Can mean embeddings characterize probabilities?

Question: Given two probability distributions $\mathbb{P}$ and $\mathbb{Q}$ with mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$, can we confidently tell if $\mathbb{P}$ and $\mathbb{Q}$ are different or not based only on the summary given by $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ ?
Example 1: Linear kernel $K\left(x, x^{\prime}\right)=x^{\top} x^{\prime}$.
Two Gaussians with different variances

$$
\begin{aligned}
\mu_{\mathbb{P}}(x) & =\mathbb{E}_{X \sim \mathbb{P}}[X]^{\top} x \\
& = \\
\mu_{\mathbb{Q}}(x) & =\mathbb{E}_{X \sim \mathbb{Q}}[X]^{\top} x
\end{aligned}
$$

## Can mean embeddings characterize probabilities?

Question: Given two probability distributions $\mathbb{P}$ and $\mathbb{Q}$ with mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$, can we confidently tell if $\mathbb{P}$ and $\mathbb{Q}$ are different or not based only on the summary given by $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ ?
Example 2: Polynomial kernel $K\left(x, x^{\prime}\right)=\left(x^{\top} x^{\prime}\right)^{2}$.

## Can mean embeddings characterize probabilities?

Question: Given two probability distributions $\mathbb{P}$ and $\mathbb{Q}$ with mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$, can we confidently tell if $\mathbb{P}$ and $\mathbb{Q}$ are different or not based only on the summary given by $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ ?
Example 2: Polynomial kernel of order 2: $K\left(x, x^{\prime}\right)=\left(x^{\top} x^{\prime}\right)^{2}$.
Gaussian and Laplace densities

$$
\begin{aligned}
\mu_{\mathbb{P}}(x) & =\operatorname{Tr}\left(\mathbb{E}_{X \sim \mathbb{P}}\left[X X^{\top}\right] x x^{\top}\right) \\
& = \\
\mu_{\mathbb{Q}}(x) & =\operatorname{Tr}\left(\mathbb{E}_{X \sim \mathbb{Q}}\left[X X^{\top}\right] x x^{\top}\right)
\end{aligned}
$$

## Can mean embeddings characterize probabilities?

Question: Are there kernels for which two mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ are equal iff $\mathbb{P}=\mathbb{Q}$ ?
Example 3: Exponential kernel $K(x, y)=\exp \left(x^{\top} y\right)$.

$$
\mu_{\mathbb{P}}(y)=\mathbb{E}_{X \sim \mathbb{P}}\left[\exp \left(X^{\top} y\right)\right]
$$

## Can mean embeddings characterize probabilities?

Question: Are there kernels for which two mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ are equal iff $\mathbb{P}=\mathbb{Q}$ ?
Example 3: Exponential kernel $K(x, y)=\exp \left(x^{\top} y\right)$.

$$
\mu_{\mathbb{P}}(y)=\underbrace{\mathbb{E}_{X \sim \mathbb{P}}\left[\exp \left(X^{\top} y\right)\right]}_{\text {Moment generating function }}
$$

## Can mean embeddings characterize probabilities?

Question: Are there kernels for which two mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ are equal iff $\mathbb{P}=\mathbb{Q}$ ?
Example 3: Exponential kernel $K(x, y)=\exp \left(x^{\top} y\right)$.

$$
\mu_{\mathbb{P}}(y)=\underbrace{\mathbb{E}_{X \sim \mathbb{P}}\left[\exp \left(X^{\top} y\right)\right]}_{\text {Moment generating function }}
$$

Classical result: If two probability distributions $\mathbb{P}$ and $\mathbb{Q}$ have the same moment generating functions, then $\mathbb{P}=\mathbb{Q}$, meaning that:

$$
\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)], \quad \forall f \in \mathcal{C}_{b}(\mathcal{X}) .
$$

## Can mean embeddings characterize probabilities?

Question: Are there kernels for which two mean embeddings $\mu_{\mathbb{P}}$ and $\mu_{\mathbb{Q}}$ are equal iff $\mathbb{P}=\mathbb{Q}$ ?
Example 3: Exponential kernel $K(x, y)=\exp \left(x^{\top} y\right)$.

$$
\mu_{\mathbb{P}}(y)=\underbrace{\mathbb{E}_{X \sim \mathbb{P}}\left[\exp \left(X^{\top} y\right)\right]}_{\text {Moment generating function }}
$$

Classical result: If two probability distributions $\mathbb{P}$ and $\mathbb{Q}$ have the same moment generating functions, then $\mathbb{P}=\mathbb{Q}$, meaning that:

$$
\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)], \quad \forall f \in \mathcal{C}_{b}(\mathcal{X})
$$

Intuitively: The RKHS and, in particular, the set of functions $\left\{K_{y}: x \mapsto \exp \left(x^{\top} y\right)\right\}_{y \in \mathcal{X}}$ is rich enough so that $\mathbb{E}_{\mathbb{P}}\left[K_{y}(X)\right]=\mathbb{E}_{\mathbb{Q}}\left[K_{y}(X)\right]$ for all $y \in \mathcal{X}$ guarantees that $\mathbb{P}=\mathbb{Q}$.

## Characteristic kernels

## Definition

Let $\mathcal{X}$ be a topological set and $\mathcal{P}$ the set of Borel probability measures on $\mathcal{X}$. Consider a bounded measurable p.d. kernel $K$ defined on $\mathcal{X}$ and let $\mathcal{H}$ be its RKHS. The kernel $K$ is said to be characteristic if the map $\mathcal{P} \ni \mathbb{P} \mapsto \mu_{\mathbb{P}}=\mathbb{E}_{X \sim \mathbb{P}}\left[K_{X}\right] \in \mathcal{H}$ is injective, i.e.:

$$
\forall \mathbb{P}, \mathbb{Q} \in \mathcal{P}: \mu_{\mathbb{P}}=\mu_{\mathbb{Q}} \Longrightarrow \mathbb{P}=\mathbb{Q}
$$

- Equality of mean embeddings $\Longleftrightarrow$ equality of expectations of functions in $\mathcal{H}$, i.e.:

$$
\mu_{\mathbb{P}}=\mu_{\mathbb{Q}} \Longleftrightarrow \mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)], \quad \forall f \in \mathcal{H}
$$

## Characteristic kernels

## Definition

$$

- A kernel $K$ is characteristic if RKHS $\mathcal{H}$ is rich enough!

## Characteristic kernels via Universality

## Definition

Let $K$ be a p.d. kernel with RKHS $\mathcal{H}$ on a compact set $\mathcal{X}$. $K$ is universal if $y \mapsto K(x, y)$ is continuous for all $x \in \mathcal{X}$ and $\mathcal{H}$ is dense in $\mathcal{C}(\mathcal{X})$ in the maximum norm $\|\cdot\|_{\infty}$.

## Characteristic kernels via Universality

## Definition

Let $K$ be a p.d. kernel with RKHS $\mathcal{H}$ on a compact set $\mathcal{X}$. $K$ is universal if $y \mapsto K(x, y)$ is continuous for all $x \in \mathcal{X}$ and $\mathcal{H}$ is dense in $\mathcal{C}(\mathcal{X})$ in the maximum norm $\|\cdot\|_{\infty}$.

## Proposition

Assume $\mathcal{X}$ is compact. If $K$ is universal, then $K$ is characteristic.

## Characteristic kernels via Universality

## Definition

Let $K$ be a p.d. kernel with RKHS $\mathcal{H}$ on a compact set $\mathcal{X}$. $K$ is universal if $y \mapsto K(x, y)$ is continuous for all $x \in \mathcal{X}$ and $\mathcal{H}$ is dense in $\mathcal{C}(\mathcal{X})$ in the maximum norm $\|.\|_{\infty}$.

## Proposition

Assume $\mathcal{X}$ is compact. If $K$ is universal, then $K$ is characteristic. proof: Let $\mathbb{P}$ and $\mathbb{Q}$ such that $\mu_{\mathbb{P}}=\mu_{\mathbb{Q}}$. We need to show that

$$
\mathbb{E}_{X \sim \mathbb{P}}[f(X)]=\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)], \forall f \in \mathcal{C}(\mathcal{X}) .
$$

Fix $f \in \mathcal{C}(\mathcal{X})$. By universality of $K, \mathcal{H}$ is dense in $\mathcal{C}(\mathcal{X})$ in the sup norm. Hence, for any $\epsilon>0$, there exists $g \in \mathcal{H}$ such that $\|f-g\|_{\infty} \leq \epsilon$.

## Characteristic kernels via Universality

Proof Next we make the expansion

$$
\begin{aligned}
\left|\mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]\right| \leq & \left|\mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{X \sim \mathbb{P}}[g(X)]\right| \\
& +\left|\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]-\mathbb{E}_{Y \sim \mathbb{Q}}[g(Y)]\right| \\
& +\left|\mathbb{E}_{X \sim \mathbb{P}}[g(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[g(Y)]\right| .
\end{aligned}
$$

The first two terms are upper-bounded by $\epsilon$ by definition of $g$. The last term is equal to 0 since $\mathbb{E}_{X \sim \mathbb{P}}[g(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[g(Y)]=\left\langle g, \mu_{\mathbb{P}}-\mu_{\mathbb{Q}}\right\rangle_{\mathcal{H}}$ and $\mu_{\mathbb{P}}=\mu_{\mathbb{Q}}$ by assumption.
Hence, we have shown that for any $\epsilon>0$ :

$$
\left|\mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]\right| \leq 2 \epsilon
$$

directly implying that $\left|\mathbb{E}_{X \sim \mathbb{P}}[f(X)]-\mathbb{E}_{Y \sim \mathbb{Q}}[f(Y)]\right|=0$.
The above holds for any $f \in \mathcal{C}(\mathcal{X})$, meaning that $\mathbb{P}=\mathbb{Q}$.

## Criteria for Universality

## Proposition

Let $0<r \leq \infty$ and $f:(-r, r) \rightarrow \mathbb{R}$ be a $C^{\infty}$ function that admits an expansion as a Taylor series in 0: $f(x)=\sum_{i=0}^{\infty} a_{i} x^{i}$. Let $\mathcal{X}$ be a compact set in the open centered ball in $\mathbb{R}^{d}$ of radius $\sqrt{r}$. If $a_{i}>0$ for all $i \geq 0$, then $k(x, y)=f(\langle x, y\rangle)$ defines a universal kernel on $\mathcal{X}$.

## Criteria for Universality

## Proposition

Let $0<r \leq \infty$ and $f:(-r, r) \rightarrow \mathbb{R}$ be a $C^{\infty}$ function that admits an expansion as a Taylor series in 0: $f(x)=\sum_{i=0}^{\infty} a_{i} x^{i}$. Let $\mathcal{X}$ be a compact set in the open centered ball in $\mathbb{R}^{d}$ of radius $\sqrt{r}$. If $a_{i}>0$ for all $i \geq 0$, then $k(x, y)=f(\langle x, y\rangle)$ defines a universal kernel on $\mathcal{X}$.

Example 1: Exp kernel: $K(x, y)=\exp \langle x, y\rangle$ on any compact $\mathcal{X}$.

$$
f(x)=\exp (x)=\sum_{i=0}^{\infty} \frac{1}{i!} x^{i}, \quad K(x, y)=f(\langle x, y\rangle)
$$

## Criteria for Universality

## Proposition

Let $0<r \leq \infty$ and $f:(-r, r) \rightarrow \mathbb{R}$ be a $C^{\infty}$ function that admits an expansion as a Taylor series in 0: $f(x)=\sum_{i=0}^{\infty} a_{i} x^{i}$. Let $\mathcal{X}$ be a compact set in the open centered ball in $\mathbb{R}^{d}$ of radius $\sqrt{r}$. If $a_{i}>0$ for all $i \geq 0$, then $k(x, y)=f(\langle x, y\rangle)$ defines a universal kernel on $\mathcal{X}$.

Example 1: Exp kernel: $K(x, y)=\exp \langle x, y\rangle$ on any compact $\mathcal{X}$.

$$
f(x)=\exp (x)=\sum_{i=0}^{\infty} \frac{1}{i!} x^{i}, \quad K(x, y)=f(\langle x, y\rangle)
$$

Example 2: Gaussian kernel on the Unit Sphere $K(x, y)=\exp \left(-\frac{1}{2}\|x-y\|^{2}\right)$.

$$
f(x)=e^{-1} \exp (x)=e^{-1} \sum_{i=0}^{\infty} \frac{1}{i!} x^{i}, \quad K(x, y)=f(\langle x, y\rangle)
$$

## Criteria for Universality

## Proposition (Steinwart 2001)

Let $f:[0,2 \pi] \rightarrow \mathbb{R}$ be a continuous function that can be expanded in a pointwise absolutely convergent Fourier series: $f(t)=\sum_{n=0}^{\infty} a_{n} \cos (n t)$. If $a_{n}>0$ for all $n \geq 0$, then the Kernel $K(x, y):=\prod_{i=1}^{d} f\left(\left|x_{i}-y_{i}\right|\right)$ defines a universal kernel on every compact subset of $[0,2 \pi)^{d}$.

## Criteria for Universality

## Proposition (Steinwart 2001)

Let $f:[0,2 \pi] \rightarrow \mathbb{R}$ be a continuous function that can be expanded in a pointwise absolutely convergent Fourier series: $f(t)=\sum_{n=0}^{\infty} a_{n} \cos (n t)$. If $a_{n}>0$ for all $n \geq 0$, then the Kernel $K(x, y):=\prod_{i=1}^{d} f\left(\left|x_{i}-y_{i}\right|\right)$ defines a universal kernel on every compact subset of $[0,2 \pi)^{d}$.

Example 1: The stronger regularized Fourier kernel (Vapnik 1998, p.470)

$$
k(x, y)=\left(1-q^{2}\right) /\left(2-4 q \cos (x-y)+2 q^{2}\right)
$$

for any $0<q<1$.

## Just in case ...

## Definition

Let $A$ be a vector space and $\times: A \times A \rightarrow A$ be a binary operation on $A$. Then $A$ is an algebra if $x$ is bilinear, i.e. for all $x, y, z \in A$ and $a, b \in \mathbb{R}$ :

$$
\begin{aligned}
& z \times(x+y)=z \times x+z \times y \\
& (x+y) \times z=x \times z+y \times z \\
& (a x) \times(b y)=(a b)(x \times y)
\end{aligned}
$$

## Theorem: Stone-Weierstrass

Let $(\mathcal{X}, d)$ be a compact metric space and $A$ a linear subspace of $\mathcal{C}(\mathcal{X})$. Then $A$ is dense in $\mathcal{C}(\mathcal{X})$ if

- $A$ is an algebra for the product of functions.
- $A$ does not vanish: For all $x \in \mathcal{X}$, there exists $f \in A$ s.t. $f(x) \neq 0$.
- $A$ separates points: For all $x, y \in \mathcal{X}$ with $x \neq y$, there exists $f \in A$, s.t. $f(x) \neq f(y)$.

## General criterion for Universality

Theorem: General criterion for universality (Steinwart, 2001)
Let $\mathcal{X}$ be a compact metric space and $k$ be a continuous kernel on $\mathcal{X}$ with $k(x, x)>0$. Suppose there is an injective map $\Phi(x)=\left\{\varphi_{i}(x)\right\}_{i \geq 0}$ such that $k(x, y)=\sum_{i=0}^{\infty} \varphi_{i}(x) \varphi_{i}(y)$. If the set $A:=\operatorname{span}\left\{\varphi_{i} \mid i \geq 0\right\}$ is an algebra, then $k$ is universal.

## General criterion for Universality

## Theorem: General criterion for universality (Steinwart, 2001)

Let $\mathcal{X}$ be a compact metric space and $k$ be a continuous kernel on $\mathcal{X}$ with $k(x, x)>0$. Suppose there is an injective map $\Phi(x)=\left\{\varphi_{i}(x)\right\}_{i \geq 0}$ such that $k(x, y)=\sum_{i=0}^{\infty} \varphi_{i}(x) \varphi_{i}(y)$. If the set $A:=\operatorname{span}\left\{\varphi_{i} \mid i \geq 0\right\}$ is an algebra, then $k$ is universal.

## Proof:

- $A$ is a subset of $\mathcal{C}(\mathcal{X})$. Follows by continuity of the map $x \mapsto \Phi(x)$. Indeed, $\|\Phi(x)-\Phi(y)\|^{2}=K(x, x)+K(y, y)-2 K(x, y) \leq \epsilon$ for any $\epsilon>0$ provided that $y$ is close enough to $x$ since $K$ is continuous.
- A does not vanish. Otherwise, we can find $x$ such that $\varphi_{i}(x)=0$ for all $i \geq 0$, meaning that $K(x, x)=0$ : contradicts $K(x, x)>0$.
- A separates points. Otherwise, there exists $x, y$ with $x \neq y$ and $\varphi_{i}(x)=\varphi_{i}(y)$ for all $i \geq 0$, hence $\Phi(x)=\Phi(y)$ : contradicts $\Phi$ injective. Hence $A$ is dense in $\mathcal{C}(\mathcal{X})$ by Stone-Weierstrass theorem.

## General criterion for Universality

## Theorem: General criterion for universality (Steinwart, 2001)

Let $\mathcal{X}$ be a compact metric space and $k$ be a continuous kernel on $\mathcal{X}$ with $k(x, x)>0$. Suppose there is an injective map $\Phi(x)=\left\{\varphi_{i}(x)\right\}_{i \geq 0}$ such that $k(x, y)=\sum_{i=0}^{\infty} \varphi_{i}(x) \varphi_{i}(y)$. If the set $A:=\operatorname{span}\left\{\varphi_{i} \mid i \geq 0\right\}$ is an algebra, then $k$ is universal.

Proof Continued: Let $f \in \mathcal{C}(\mathcal{X})$ and $\epsilon>0$.

- Since $A$ is dense in $\mathcal{C}(\mathcal{X})$, there exists $g \in A$ s.t. $\|f-g\|_{\infty}<\epsilon$.
- By definition of $A$, the function $g$ is of the form $g(x)=\langle w, \Phi(x)\rangle_{l_{2}}$ with $w=\left(w_{i}\right)_{i \geq 0}$ s.t. $w_{i}=0$ for any $i>N$ for some $N<\infty$.
- Hence, $g$ belongs to the unique RKHS $\mathcal{H}$ of $K$. This shows that $\mathcal{H}$ is dense in $\mathcal{C}(\mathcal{X})$, hence $K$ is universal.

## Criteria for Universality

## Proposition

Let $0<r \leq \infty$ and $f:(-r, r) \rightarrow \mathbb{R}$ be a $C^{\infty}$ function that admits an expansion as a Taylor series in 0: $f(x)=\sum_{i=0}^{\infty} a_{i} x^{i}$. Let $\mathcal{X}$ be a compact set in the open centered ball in $\mathbb{R}^{d}$ of radius $\sqrt{r}$. If $a_{i}>0$ for all $i \geq 0$, then $k(x, y)=f(\langle x, y\rangle)$ defines a universal kernel on $\mathcal{X}$.

## Criteria for Universality

## Proposition

Let $0<r \leq \infty$ and $f:(-r, r) \rightarrow \mathbb{R}$ be a $C^{\infty}$ function that admits an expansion as a Taylor series in 0: $f(x)=\sum_{i=0}^{\infty} a_{i} x^{i}$. Let $\mathcal{X}$ be a compact set in the open centered ball in $\mathbb{R}^{d}$ of radius $\sqrt{r}$. If $a_{i}>0$ for all $i \geq 0$, then $k(x, y)=f(\langle x, y\rangle)$ defines a universal kernel on $\mathcal{X}$.

Proof: For simplicity, take $d=1$.

- $K$ is continuous and of the form:

$$
\left.K(x, y):=\sum_{i=0}^{\infty} a_{i} x^{i} y^{i}=\langle\Phi(x), \Phi(y)\rangle\right\rangle_{2}
$$

with $\Phi(x)=\left(\sqrt{a_{i}} x^{i}\right)_{i \geq 0}$ which is injective.

- $K(x, x)=\sum_{i=0}^{\infty} a_{i} x^{2 i}>0$ since $a_{i}>0$ for all $i \geq 0$.
- $A:=\operatorname{span}\left(\left\{\varphi_{n} \mid n \geq 0\right\}\right)$ is the algebra of polynomials.
- Hence $K$ universal by the general criterion for universality.

## Criteria for Universality

## Proposition (Steinwart 2001)

Let $f:[0,2 \pi] \rightarrow \mathbb{R}$ be a continuous function that can be expanded in a pointwise absolutely convergent Fourier series: $f(t)=\sum_{n=0}^{\infty} a_{n} \cos (n t)$. If $a_{n}>0$ for all $n \geq 0$, then the Kernel $K(x, y):=\prod_{i=1}^{d} f\left(\left|x_{i}-y_{i}\right|\right)$ defines a universal kernel on every compact subset of $[0,2 \pi)^{d}$.

## Criteria for Universality

## Proposition (Steinwart 2001)

Let $f:[0,2 \pi] \rightarrow \mathbb{R}$ be a continuous function that can be expanded in a pointwise absolutely convergent Fourier series: $f(t)=\sum_{n=0}^{\infty} a_{n} \cos (n t)$. If $a_{n}>0$ for all $n \geq 0$, then the Kernel $K(x, y):=\prod_{i=1}^{d} f\left(\left|x_{i}-y_{i}\right|\right)$ defines a universal kernel on every compact subset of $[0,2 \pi)^{d}$.

Proof: For simplicity, take $d=1$.

- $K$ is continuous and of the form:
$K(x, y)=a_{0}+\sum_{n=0}^{\infty} a_{n}(\sin (n x) \sin (n y)+\cos (n x) \cos (n y))=\langle\Phi(x), \Phi(y)\rangle_{l_{2}}$
where $\Phi(x)=\left(\varphi_{n}(x)\right)_{n \geq 0}$ defined by $\varphi_{0}(x)=a_{0}, \varphi_{2 n-1}=\sqrt{a_{n}} \sin (n x)$ and $\varphi_{2 n}(x)=\sqrt{a_{n}} \cos (n x)$ for $n \geq 1$ is injective.
- $K(x, x)=\sum_{n=0}^{\infty} a_{n}>0$ since $a_{n}>0$ for all $n \geq 0$.
- $A:=\operatorname{span}\left(\left\{\varphi_{n} \mid n \geq 0\right\}\right)$ is an algebra (by trigonometric identities).
- Hence $K$ universal by the general criterion for universality.

## Summary: Characteristic kernels via Universality

- On a compact metric set $\mathcal{X}$, a universal kernel is a continuous kernel whose RKHS $(H)$ is dense in $\mathcal{C}(\mathcal{X})$ in the maximum norm.
- Any universal kernel on $\mathcal{X}$ is characteristic, i.e. the mean embedding map $\mathbb{P} \mapsto \mu_{\mathbb{P}}=\mathbb{E}_{X \sim \mathbb{P}}\left[K_{X}\right] \in \mathcal{H}$ defined on the set $\mathcal{P}$ of probability distributions on $\mathcal{X}$ is injective:

$$
\forall \mathbb{P}, \mathbb{Q} \in \mathcal{P}: \mu_{\mathbb{P}}=\mu_{\mathbb{Q}} \Longrightarrow \mathbb{P}=\mathbb{Q}
$$

- Can construct a large class of universal kernels using Taylor series or Fourier series with positive coefficients.
- Both constructions follow from the General criterion for universality, itself a consequence of Stone-Weierstrass theorem for compact metric sets.
- Question: What if $\mathcal{X}$ is not compact?

## Characteristic kernels via Fourier transform

- Consider a translation invariant kernel $K$ on $\mathbb{R}^{d}$ of the form $K(x, y)=\kappa(x-y)$ with $\kappa: \mathbb{R}^{d} \rightarrow \mathbb{R}$.

## Characteristic kernels via Fourier transform

- Consider a translation invariant kernel $K$ on $\mathbb{R}^{d}$ of the form $K(x, y)=\kappa(x-y)$ with $\kappa: \mathbb{R}^{d} \rightarrow \mathbb{R}$.
- Bochner's theorem implies the existence of a finite non-negative Borel measure $\Lambda$ on $\mathbb{R}^{d}$ such that $\kappa(z)=\int e^{-i z^{\top} w} d \Lambda(w)$.

## Characteristic kernels via Fourier transform

- Consider a translation invariant kernel $K$ on $\mathbb{R}^{d}$ of the form $K(x, y)=\kappa(x-y)$ with $\kappa: \mathbb{R}^{d} \rightarrow \mathbb{R}$.
- Bochner's theorem implies the existence of a finite non-negative Borel measure $\Lambda$ on $\mathbb{R}^{d}$ such that $\kappa(z)=\int e^{-i z^{\top} w} d \Lambda(w)$.
- Can express $K$ as a Hermitian product in $L_{2}(\Lambda)$ of Fourier features:

$$
K(x, y)=\langle\Phi(x), \Phi(y)\rangle_{L_{2}(\Lambda)}, \quad w \mapsto \Phi(x)(w)=e^{-i x^{\top} w}
$$

$$

- Can express the mean embedding $\mu_{\mathbb{P}}$ in terms of $\mathcal{F}(\mathbb{P})=\mathbb{E}_{X \sim \mathbb{P}}[\Phi(X)]$ the of Fourier transform of $\mathbb{P}$ :

$$
\mu_{\mathbb{P}}(y)=\mathbb{E}_{X \sim \mathbb{P}}\left[\langle\Phi(X), \Phi(y)\rangle_{L_{2}(\Lambda)}\right]=\langle\mathcal{F}(\mathbb{P}), \Phi(y)\rangle_{L_{2}(\Lambda)}
$$

## Fourier inversion theorem (Dudley 2002, Theorem 9.5.4)

If $\mathbb{P}$ and $\mathbb{Q}$ are two probability distributions on $\mathbb{R}^{d}$ with the same Fourier transform: $\mathcal{F}(\mathbb{P})=\mathcal{F}(\mathbb{Q})$, then $\mathbb{P}=\mathbb{Q}$.

The measure $\Lambda$ must "preserve information contained" in the Fourier transform $\mathcal{F}(\mathbb{P})$.

## Characteristic kernels via Fourier transform

## Translation invariant characteristic kernels: (Sriperumbudur 2008)

Let $K$ be a translation invariant kernel on $\mathbb{R}^{d}$ of the form $K(x, y)=\kappa(x-y)$ with $\kappa(z)=\int e^{-i z^{\top} w} d \Lambda(w)$ for some finite non-negative Borel measure $\Lambda$ on $\mathbb{R}^{d}$. The kernel $K$ is characteristic if and only if $\operatorname{supp}(\Lambda)=\mathbb{R}^{d}$.

## Characteristic kernels via Fourier transform

## Translation invariant characteristic kernels: (Sriperumbudur 2008)

Let $K$ be a translation invariant kernel on $\mathbb{R}^{d}$ of the form $K(x, y)=\kappa(x-y)$ with $\kappa(z)=\int e^{-i z^{\top} w} d \Lambda(w)$ for some finite non-negative Borel measure $\Lambda$ on $\mathbb{R}^{d}$. The kernel $K$ is characteristic if and only if $\operatorname{supp}(\Lambda)=\mathbb{R}^{d}$.
Example 1: Gaussian kernel $K(x, y)=e^{-\frac{\sigma^{2}}{2}\|x-y\|^{2}}$. The measure $\Lambda$ is a gaussian on $\mathbb{R}^{d}$ with density $w \mapsto \sqrt{2 \pi \sigma^{2}} e^{-\frac{1}{2 \sigma^{2}}\|w\|^{2}}$. Since $\operatorname{supp}(\Lambda)=\mathbb{R}^{d}, K$ is characteristic.

## Characteristic kernels via Fourier transform

## Translation invariant characteristic kernels: (Sriperumbudur 2008)

Let $K$ be a translation invariant kernel on $\mathbb{R}^{d}$ of the form $K(x, y)=\kappa(x-y)$ with $\kappa(z)=\int e^{-i z^{\top} w} d \Lambda(w)$ for some finite non-negative Borel measure $\Lambda$ on $\mathbb{R}^{d}$. The kernel $K$ is characteristic if and only if $\operatorname{supp}(\Lambda)=\mathbb{R}^{d}$.
Example 1: Gaussian kernel $K(x, y)=e^{-\frac{\sigma^{2}}{2}\|x-y\|^{2}}$. The measure $\Lambda$ is a gaussian on $\mathbb{R}^{d}$ with density $w \mapsto \sqrt{2 \pi \sigma^{2}} e^{-\frac{1}{2 \sigma^{2}}\|w\|^{2}}$. Since $\operatorname{supp}(\Lambda)=\mathbb{R}^{d}, K$ is characteristic.
Example 2: Let $k(z)=\|z\|^{-\frac{d}{2}} J_{d / 2}(\|z\|)$, where $J_{p}$ is Bessel's function of the first kind. Then $K(x, y)=\kappa(x-y)$ is not characteristic: $\Lambda$ is the uniform distribution on the unit ball.

## Characteristic kernels via Fourier transform

- Bochner's theorem: A translation invariant kernel on $\mathbb{R}^{d}$ is characterized by unique finite non-negative measure $\Lambda$
- Main result: $K$ is characteristic if and only if $\operatorname{supp}(\Lambda)=\mathbb{R}^{d}$.
- Similar reasoning can be applied to any space where Bochner's theorem holds:
- Locally compact Abelian groups
- Compact, non-Abelian groups (orthogonal matrices)
- The semigroup $\mathbb{R}_{+}^{d}$.

## Characteristic kernels: Summary

## Definition

Let $\mathcal{X}$ be a topological set and $\mathcal{P}$ the set of Borel probability measures on $\mathcal{X}$. Consider a bounded measurable p.d. kernel $K$ defined on $\mathcal{X}$ and let $\mathcal{H}$ be its RKHS. The kernel $K$ is said to be characteristic if the map $\mathcal{P} \ni \mathbb{P} \mapsto \mu_{\mathbb{P}}=\mathbb{E}_{X \sim \mathbb{P}}\left[K_{X}\right] \in \mathcal{H}$ is injective, i.e.:

$$
\forall \mathbb{P}, \mathbb{Q} \in \mathcal{P}: \mu_{\mathbb{P}}=\mu_{\mathbb{Q}} \Longrightarrow \mathbb{P}=\mathbb{Q}
$$

Criteria for characteristic kernels

- On a compact set $\mathcal{X}$, can use criteria for universality: A kernel is universal if it continuous and its RKHS is dense in $\mathcal{C}(\mathcal{X})$.
- If $K$ admits a Taylor expansion with positive coefficients.
- If $K$ admits a Fourier expansion with positive coefficients.
- If $\mathcal{X}=\mathbb{R}^{d}$ and $K$ is translation invariant with associated non-negative measure $\Lambda: K$ characteristic $\Longleftrightarrow \operatorname{supp}(\Lambda)=\mathbb{R}^{d}$

(6) Open Problems and Research Topics

- Multiple Kernel Learning (MKL)
- Large-scale learning with kernels
- Foundations of deep learning from a kernel point of view

## Motivation

- We have seen how to make learning algorithms given a kernel $K$ on some data space $\mathcal{X}$
- Often we may have several possible kernels:
- by varying the kernel type or parameters on a given description of the data (eg, linear, polynomial, Gaussian kernels with different bandwidths...)
- because we have different views of the same data, eg, a protein can be characterized by its sequence, its structure, its mass spectrometry profile...
- How to choose or integrate different kernels in a learning task?

## Setting: learning with one kernel

- For any $f: \mathcal{X} \rightarrow \mathbb{R}$, let $f^{n}=\left(f\left(\mathbf{x}_{1}\right), \ldots, f\left(\mathbf{x}_{n}\right)\right) \in \mathbb{R}^{n}$
- Given a p.d. kernel $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$, we learn with $K$ by solving:

$$
\begin{equation*}
\min _{f \in \mathcal{H}} R\left(f^{n}\right)+\lambda\|f\|_{\mathcal{H}}^{2} \tag{4}
\end{equation*}
$$

where $\lambda>0$ and $R: \mathbb{R}^{n} \rightarrow \mathbb{R}$ is an closed ${ }^{3}$ and convex empirical risk:

- $R(u)=\frac{1}{n} \sum_{i=1}^{n}\left(u_{i}-y_{i}\right)^{2}$ for kernel ridge regression
- $R(u)=\frac{1}{n} \sum_{i=1}^{n} \max \left(1-y_{i} u_{i}, 0\right)$ for SVM
- $R(u)=\frac{1}{n} \sum_{i=1}^{n} \log \left(1+\exp \left(-y_{i} u_{i}\right)\right)$ for kernel logistic regression

[^2]
## Sum kernel

## Definition

Let $K_{1}, \ldots, K_{M}$ be $M$ kernels on $\mathcal{X}$. The sum kernel $K_{S}$ is the kernel on $\mathcal{X}$ defined as

$$
\forall \mathbf{x}, \mathbf{x}^{\prime} \in \mathcal{X}, \quad K_{S}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{i=1}^{M} K_{i}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)
$$

## Sum kernel and vector concatenation

## Theorem

For $i=1, \ldots, M$, let $\Phi_{i}: \mathcal{X} \rightarrow \mathcal{H}_{i}$ be a feature map such that

$$
K_{i}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\left\langle\Phi_{i}(\mathbf{x}), \Phi_{i}\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}_{i}}
$$

Then $K_{S}=\sum_{i=1}^{M} K_{i}$ can be written as:

$$
K_{S}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\left\langle\Phi_{S}(\mathbf{x}), \Phi_{S}\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}_{S}},
$$

where $\Phi_{S}: \mathcal{X} \rightarrow \mathcal{H}_{S}=\mathcal{H}_{1} \oplus \ldots \oplus \mathcal{H}_{M}$ is the concatenation of the feature maps $\Phi_{i}$ :

$$
\Phi_{S}(\mathbf{x})=\left(\Phi_{1}(\mathbf{x}), \ldots, \Phi_{M}(\mathbf{x})\right)^{\top} .
$$

Therefore, summing kernels amounts to concatenating their feature space representations, which is a quite natural way to integrate different features.

## Proof

For $\Phi_{S}(\mathbf{x})=\left(\Phi_{1}(\mathbf{x}), \ldots, \Phi_{M}(\mathbf{x})\right)^{\top}$, we easily compute:

$$
\begin{aligned}
\left\langle\Phi_{S}(\mathbf{x}), \Phi_{S}\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}_{s}} & =\sum_{i=1}^{M}\left\langle\Phi_{i}(\mathbf{x}), \Phi_{i}\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}_{i}} \\
& =\sum_{i=1}^{M} K_{i}\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \\
& =K_{S}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)
\end{aligned}
$$

## The sum kernel: functional point of view

## Theorem

The solution $f^{*} \in \mathcal{H}_{K_{S}}$ when we learn with $K_{S}=\sum_{i=1}^{M} K_{i}$ is equal to:

$$
f^{*}=\sum_{i=1}^{M} f_{i}^{*}
$$

where $\left(f_{1}^{*}, \ldots, f_{M}^{*}\right) \in \mathcal{H}_{K_{1}} \times \ldots \times \mathcal{H}_{K_{M}}$ is the solution of:

$$
\min _{f_{1}, \ldots, f_{M}} R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda \sum_{i=1}^{M}\left\|f_{i}\right\|_{\mathcal{H}_{\kappa_{i}}}^{2} .
$$

## Generalization: The weighted sum kernel

## Theorem

The solution $f^{*}$ when we learn with $K_{\eta}=\sum_{i=1}^{M} \eta_{i} K_{i}$, with $\eta_{1}, \ldots, \eta_{M} \geq 0$, is equal to:

$$
f^{*}=\sum_{i=1}^{M} f_{i}^{*}
$$

where $\left(f_{1}^{*}, \ldots, f_{M}^{*}\right) \in \mathcal{H}_{K_{1}} \times \ldots \times \mathcal{H}_{K_{M}}$ is the solution of:

$$
\min _{f_{1}, \ldots, f_{M}} R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda \sum_{i=1}^{M} \frac{\left\|f_{i}\right\|_{\mathcal{H}_{\kappa_{i}}}^{2}}{\eta_{i}} .
$$

## Proof (1/4)

$$
\min _{f_{1}, \ldots, f_{M}} R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda \sum_{i=1}^{M} \frac{\left\|f_{i}\right\|_{\mathcal{H}_{k_{i}}}^{2}}{\eta_{i}}
$$

- $R$ being convex, the problem is strictly convex and has a unique solution $\left(f_{1}^{*}, \ldots, f_{M}^{*}\right) \in \mathcal{H}_{K_{1}} \times \ldots \times \mathcal{H}_{K_{M}}$.
- By the representer theorem, there exists $\boldsymbol{\alpha}_{1}^{*}, \ldots, \boldsymbol{\alpha}_{M}^{*} \in \mathbb{R}^{n}$ such that

$$
f_{i}^{*}(\mathbf{x})=\sum_{j=1}^{n} \alpha_{i j}^{*} K_{i}\left(\mathbf{x}_{j}, \mathbf{x}\right)
$$

- $\left(\boldsymbol{\alpha}_{1}^{*}, \ldots, \boldsymbol{\alpha}_{M}^{*}\right)$ is the solution of

$$
\min _{\boldsymbol{\alpha}_{1}, \ldots, \boldsymbol{\alpha}_{M} \in \mathbb{R}^{n}} R\left(\sum_{i=1}^{M} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}\right)+\lambda \sum_{i=1}^{M} \frac{\boldsymbol{\alpha}_{i}^{\top} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}}{\eta_{i}}
$$

## Proof (2/4)

- This is equivalent to

$$
\min _{\mathbf{u}, \boldsymbol{\alpha}_{1}, \ldots, \boldsymbol{\alpha}_{M} \in \mathbb{R}^{n}} R(\mathbf{u})+\lambda \sum_{i=1}^{M} \frac{\boldsymbol{\alpha}_{i}^{\top} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}}{\eta_{i}} \quad \text { s.t. } \quad u=\sum_{i=1}^{M} \mathbf{K}_{i} \boldsymbol{\alpha}_{i} .
$$

- This is equivalent to the saddle point problem:

$$
\min _{\mathbf{u}, \boldsymbol{\alpha}_{1}, \ldots, \boldsymbol{\alpha}_{M} \in \mathbb{R}^{n}} \max _{\boldsymbol{\gamma} \in \mathbb{R}^{n}} R(\mathbf{u})+\lambda \sum_{i=1}^{M} \frac{\boldsymbol{\alpha}_{i}^{\top} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}}{\eta_{i}}+2 \lambda \boldsymbol{\gamma}^{\top}\left(\mathbf{u}-\sum_{i=1}^{M} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}\right)
$$

- By Slater's condition, strong duality holds, meaning we can invert min and max:

$$
\max _{\gamma \in \mathbb{R}^{n}} \min _{\mathbf{u}, \boldsymbol{\alpha}_{1}, \ldots, \boldsymbol{\alpha}_{M} \in \mathbb{R}^{n}} R(\mathbf{u})+\lambda \sum_{i=1}^{M} \frac{\boldsymbol{\alpha}_{i}^{\top} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}}{\eta_{i}}+2 \lambda \boldsymbol{\gamma}^{\top}\left(\mathbf{u}-\sum_{i=1}^{M} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}\right)
$$

## Proof (3/4)

- Minimization in $\mathbf{u}$ :

$$
\min _{u} R(\mathbf{u})+2 \lambda \gamma^{\top} \mathbf{u}=-\max _{\mathbf{u}}\left\{-2 \lambda \gamma^{\top} \mathbf{u}-R(\mathbf{u})\right\}=-R^{*}(-2 \lambda \gamma)
$$

where $R^{*}$ is the Fenchel dual of $R$ :

$$
\forall \mathbf{v} \in \mathbb{R}^{n} \quad R^{*}(\mathbf{v})=\sup _{\mathbf{u} \in \mathbb{R}^{n}} \mathbf{u}^{\top} \mathbf{v}-R(\mathbf{u}) .
$$

- Minimization in $\boldsymbol{\alpha}_{i}$ for $i=1, \ldots, M$ :

$$
\min _{\boldsymbol{\alpha}_{i}}\left\{\lambda \frac{\boldsymbol{\alpha}_{i}^{\top} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}}{\eta_{i}}-2 \lambda \gamma^{\top} \mathbf{K}_{i} \boldsymbol{\alpha}_{i}\right\}=-\lambda \eta_{i} \gamma^{\top} \mathbf{K}_{i} \gamma
$$

where the minimum in $\boldsymbol{\alpha}_{i}$ is reached for $\alpha_{i}^{*}=\eta_{i} \gamma$.

## Proof (4/4)

- The dual problem is therefore

$$
\max _{\gamma \in \mathbb{R}^{n}}\left\{-R^{*}(-2 \lambda \gamma)-\lambda \gamma^{\top}\left(\sum_{i=1}^{M} \eta_{i} \mathbf{K}_{i}\right) \gamma\right\} .
$$

- Note that if learn from a single kernel $\mathbf{K}_{\boldsymbol{\eta}}$, we get the same dual problem

$$
\max _{\gamma \in \mathbb{R}^{n}}\left\{-R^{*}(-2 \lambda \gamma)-\lambda \gamma^{\top} \mathbf{K}_{\eta} \gamma\right\}
$$

- If $\gamma^{*}$ is a solution of the dual problem, then $\boldsymbol{\alpha}_{i}^{*}=\eta_{i} \gamma^{*}$ leading to:

$$
\forall \mathbf{x} \in \mathcal{X}, \quad f_{i}^{*}(\mathbf{x})=\sum_{j=1}^{n} \alpha_{i j}^{*} \mathbf{K}_{i}\left(\mathbf{x}_{j}, \mathbf{x}\right)=\sum_{j=1}^{n} \eta_{i} \gamma_{j}^{*} \mathbf{K}_{i}\left(\mathbf{x}_{j}, \mathbf{x}\right)
$$

- Therefore, $f^{*}=\sum_{i=1}^{M} f_{i}^{*}$ satisfies

$$
f^{*}(\mathbf{x})=\sum_{i=1}^{M} \sum_{j=1}^{n} \eta_{i} \gamma_{j}^{*} \mathbf{K}_{i}\left(\mathbf{x}_{j}, \mathbf{x}\right)=\sum_{j=1}^{n} \gamma_{j}^{*} \mathbf{K}_{\eta}\left(\mathbf{x}_{j}, \mathbf{x}\right)
$$

## Learning the kernel

## Motivation

- If we know how to weight each kernel, then we can learn with the weighted kernel

$$
\mathbf{K}_{\eta}=\sum_{i=1}^{M} \eta_{i} \mathbf{K}_{i}
$$

- However, usually we don't know...
- Perhaps we can optimize the weights $\eta_{i}$ during learning?

## An objective function for $K$

## Theorem

For any p.d. kernel $K$ on $\mathcal{X}$, let

$$
J(K)=\min _{f \in \mathcal{H}}\left\{R\left(f^{n}\right)+\lambda\|f\|_{\mathcal{H}}^{2}\right\} .
$$

The function $K \mapsto J(K)$ is convex.
This suggests a principled way to "learn" a kernel: define a convex set of candidate kernels, and minimize $J(K)$ by convex optimization.

## Proof

- We have shown by strong duality that

$$
J(K)=\max _{\gamma \in \mathbb{R}^{n}}\left\{-R^{*}(-2 \lambda \gamma)-\lambda \gamma^{\top} \mathbf{K} \gamma\right\}
$$

- For each $\gamma$ fixed, this is an affine function of $K$, hence convex
- A supremum of convex functions is convex.

## MKL (Lanckriet et al., 2004)

- We consider the set of convex combinations

$$
K_{\eta}=\sum_{i=1}^{M} \eta_{i} K_{i} \quad \text { with } \quad \boldsymbol{\eta} \in \Sigma_{M}=\left\{\eta_{i} \geq 0, \sum_{i=1}^{M} \eta_{i}=1\right\}
$$

- We optimize both $\boldsymbol{\eta}$ and $f^{*}$ by solving:

$$
\min _{\eta \in \Sigma_{M}} J\left(K_{\eta}\right)=\min _{\eta \in \Sigma_{M}} \min _{f \in \mathcal{H} \kappa_{\eta}}\left\{R\left(f^{n}\right)+\lambda\|f\|_{\mathcal{H}_{\kappa_{\eta}}}^{2}\right\}
$$

- The problem is jointly convex in ( $\boldsymbol{\eta}, \boldsymbol{\alpha}$ ) and can be solved efficiently.
- The output is both a set of weights $\boldsymbol{\eta}$, and a predictor corresponding to the kernel method trained with kernel $K_{\eta}$.
- This method is usually called Multiple Kernel Learning (MKL).

## Example: Image classification (Harchaoui and Bach, 2007)

## COREL14 dataset

- 1400 natural images in 14 classes
- Compare kernel between histograms (H), walk kernel (W), subtree kernel (TW), weighted subtree kernel (wTW), and a combination by MKL (M).

## MKL revisited (Bach et al., 2004)

$$
K_{\eta}=\sum_{i=1}^{M} \eta_{i} K_{i} \quad \text { with } \quad \eta \in \Sigma_{M}=\left\{\eta_{i} \geq 0, \sum_{i=1}^{M} \eta_{i}=1\right\}
$$

## Theorem

The solution $f^{*}$ of

$$
\min _{\eta \in \Sigma_{M}} \min _{f \in \mathcal{H} \kappa_{\eta}}\left\{R\left(f^{n}\right)+\lambda\|f\|_{\mathcal{H}_{\kappa_{\eta}}}^{2}\right\}
$$

is $f^{*}=\sum_{i=1}^{M} f_{i}^{*}$, where $\left(f_{1}^{*}, \ldots, f_{M}^{*}\right) \in \mathcal{H}_{K_{1}} \times \ldots \times \mathcal{H}_{K_{M}}$ is the solution of:

$$
\min _{f_{1}, \ldots, f_{M}}\left\{R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda\left(\sum_{i=1}^{M}\left\|f_{i}\right\|_{\mathcal{H}_{\kappa_{i}}}\right)^{2}\right\} .
$$

## Proof (1/2)

$$
\begin{aligned}
\min _{\eta \in \Sigma_{M}} \min _{f \in \mathcal{H}_{\kappa_{\eta}}} & \left\{R\left(f^{n}\right)+\lambda\|f\|_{\mathcal{H}_{\kappa_{\eta}}}^{2}\right\} \\
& =\min _{\eta \in \Sigma_{M}} \min _{f_{1}, \ldots, f_{M}}\left\{R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda \sum_{i=1}^{M} \frac{\left\|f_{i}\right\|_{\mathcal{H}_{K_{i}}}^{2}}{\eta_{i}}\right\} \\
& =\min _{f_{1}, \ldots, f_{M}}\left\{R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda \min _{\eta \in \Sigma_{M}}\left\{\sum_{i=1}^{M} \frac{\left\|f_{i}\right\|_{\mathcal{H}_{K_{i}}}^{2}}{\eta_{i}}\right\}\right\} \\
& =\min _{f_{1}, \ldots, f_{M}}\left\{R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda\left(\sum_{i=1}^{M}\left\|f_{i}\right\|_{\mathcal{H}_{\kappa_{i}}}\right)^{2}\right\}
\end{aligned}
$$

## Proof (2/2)

where the last equality results from:

$$
\forall \mathbf{a} \in \mathbb{R}_{+}^{M}, \quad\left(\sum_{i=1}^{M} a_{i}\right)^{2}=\inf _{\eta \in \Sigma_{M}} \sum_{i=1}^{M} \frac{a_{i}^{2}}{\eta_{i}},
$$

which is a direct consequence of the Cauchy-Schwarz inequality:

$$
\sum_{i=1}^{M} a_{i}=\sum_{i=1}^{M} \frac{a_{i}}{\sqrt{\eta_{i}}} \times \sqrt{\eta_{i}} \leq\left(\sum_{i=1}^{M} \frac{a_{i}^{2}}{\eta_{i}}\right)^{\frac{1}{2}}\left(\sum_{i=1}^{M} \eta_{i}\right)^{\frac{1}{2}}
$$

## Algorithm: simpleMKL (Rakotomamonjy et al., 2008)

- We want to minimize in $\boldsymbol{\eta} \in \Sigma_{M}$ :

$$
\min _{\eta \in \Sigma_{M}} J\left(K_{\eta}\right)=\min _{\eta \in \Sigma_{M}} \max _{\gamma \in \mathbb{R}^{n}}\left\{-R^{*}(-2 \lambda \gamma)-\lambda \gamma^{\top} \mathbf{K}_{\eta} \gamma\right\}
$$

- For a fixed $\eta \in \Sigma_{M}$, we can compute $f(\boldsymbol{\eta})=J\left(K_{\eta}\right)$ by using a standard solver for a single kernel to find $\gamma^{*}$ :

$$
J\left(K_{\eta}\right)=-R^{*}\left(-2 \lambda \gamma^{*}\right)-\lambda \gamma^{* \top} \mathbf{K}_{\eta} \gamma^{*}
$$

- From $\gamma^{*}$ we can also compute the gradient of $J\left(K_{\eta}\right)$ with respect to $\eta$ :

$$
\frac{\partial J\left(K_{\eta}\right)}{\partial \eta_{i}}=-\lambda \gamma^{* \top} K_{i} \gamma^{*}
$$

- $J\left(K_{\eta}\right)$ can then be minimized on $\Sigma_{M}$ by a projected gradient or reduced gradient algorithm.

## Sum kernel vs MKL

- Learning with the sum kernel (uniform combination) solves

$$
\min _{f_{1}, \ldots, f_{M}}\left\{R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda \sum_{i=1}^{M}\left\|f_{i}\right\|_{\mathcal{H}_{k_{i}}}^{2}\right\} .
$$

- Learning with MKL (best convex combination) solves

$$
\min _{f_{1}, \ldots, f_{M}}\left\{R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda\left(\sum_{i=1}^{M}\left\|f_{i}\right\|_{\mathcal{H}_{K_{i}}}\right)^{2}\right\}
$$

- Although MKL can be thought of as optimizing a convex combination of kernels, it is more correct to think of it as a penalized risk minimization estimator with the group lasso penalty:

$$
\Omega(f)=\min _{f_{1}+\ldots+f_{M}=f} \sum_{i=1}^{M}\left\|f_{i}\right\|_{\mathcal{H}_{K_{i}}} .
$$

## Example: ridge vs LASSO regression

- Take $\mathcal{X}=\mathbb{R}^{d}$, and for $\mathbf{x}=\left(x_{1}, \ldots, x_{d}\right)^{\top}$ consider the rank- 1 kernels:

$$
\forall i=1, \ldots, d, \quad K_{i}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=x_{i} x_{i}^{\prime}
$$

- A function $f_{i} \in \mathcal{H}_{K_{i}}$ has the form $f_{i}(\mathbf{x})=\beta_{i} x_{i}$, with $\left\|f_{i}\right\|_{\mathcal{H}_{K_{i}}}=\left|\beta_{i}\right|$
- The sum kernel is $K_{S}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{i=1}^{d} x_{i} x_{i}^{\prime}=\mathbf{x}^{\top} \mathbf{x}$, a function $\mathcal{H}_{K_{S}}$ is of the form $f(\mathbf{x})=\boldsymbol{\beta}^{\top} \mathbf{x}$, with norm $\|f\|_{\mathcal{H}_{\kappa_{S}}}=\|\boldsymbol{\beta}\|_{\mathbb{R}^{d}}$.
- Learning with the sum kernel solves a ridge regression problem:

$$
\min _{\boldsymbol{\beta} \in \mathbb{R}^{d}}\left\{R(\mathbf{X} \boldsymbol{\beta})+\lambda \sum_{i=1}^{d} \beta_{i}^{2}\right\}
$$

- Learning with MKL solves a LASSO regression problem:

$$
\min _{\boldsymbol{\beta} \in \mathbb{R}^{d}}\left\{R(\mathbf{X} \boldsymbol{\beta})+\lambda\left(\sum_{i=1}^{d}\left|\beta_{i}\right|\right)^{2}\right\} .
$$

## Extensions (Micchelli et al., 2005)

For $r>0, \quad K_{\eta}=\sum_{i=1}^{M} \eta_{i} K_{i}$ with $\quad \boldsymbol{\eta} \in \Sigma_{M}^{r}=\left\{\eta_{i} \geq 0, \sum_{i=1}^{M} \eta_{i}^{r}=1\right\}$

## Theorem

The solution $f^{*}$ of

$$
\min _{\eta \in \Sigma_{M}^{\prime}} \min _{f \in \mathcal{H}_{\kappa_{\eta}}}\left\{R\left(f^{n}\right)+\lambda\|f\|_{\mathcal{H}_{\kappa_{\eta}}}^{2}\right\}
$$

is $f^{*}=\sum_{i=1}^{M} f_{i}^{*}$, where $\left(f_{1}^{*}, \ldots, f_{M}^{*}\right) \in \mathcal{H}_{K_{1}} \times \ldots \times \mathcal{H}_{K_{M}}$ is the solution of:

$$
\min _{f_{1}, \ldots, f_{M}}\left\{R\left(\sum_{i=1}^{M} f_{i}^{n}\right)+\lambda\left(\sum_{i=1}^{M}\left\|f_{i}\right\|_{\mathcal{H} \kappa_{i}}^{\frac{2 r}{r+1}}\right)^{\frac{r+1}{r}}\right\}
$$

- Multiple Kernel Learning (MKL)
- Large-scale learning with kernels
- Motivation
- Interlude: Large-scale learning with linear models
- Nyström approximations
- Random Fourier features
- Foundations of deep learning from a kernel point of view

## Motivation

## Main problem

All methods we have seen require computing the $n \times n$ Gram matrix, which is infeasible when $n$ is significantly greater than 100000 both in terms of memory and computation.

## Solutions

- low-rank approximation of the kernel;
- random Fourier features.

The goal is to find an approximate embedding $\psi: \mathcal{X} \rightarrow \mathbb{R}^{d}$ such that

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \approx\left\langle\psi(\mathbf{x}), \psi\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathbb{R}^{d}}
$$

and use large-scale optimization techniques dedicated to linear models!

## Motivation

Then, functions $f$ in $\mathcal{H}$ may be approximated by linear ones in $\mathbb{R}^{d}$, e.g.,.

$$
f(\mathbf{x})=\sum_{i=1}^{n} \alpha_{i} K\left(\mathbf{x}_{i}, \mathbf{x}\right) \approx\left\langle\sum_{i=1}^{n} \alpha_{i} \psi\left(\mathbf{x}_{i}\right), \psi(\mathbf{x})\right\rangle_{\mathbb{R}^{d}}=\langle\mathbf{w}, \psi(\mathbf{x})\rangle_{\mathbb{R}^{d}}
$$

Then, the ERM problem

$$
\min _{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)+\lambda\|f\|_{\mathcal{H}}^{2}
$$

becomes, approximately,

$$
\min _{\mathbf{w} \in \mathbb{R}^{d}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, \mathbf{w}^{\top} \psi\left(\mathbf{x}_{i}\right)\right)+\lambda\|\mathbf{w}\|_{2}^{2}
$$

which we know how to solve when $n$ is large.

## Interlude: Large-scale learning with linear models

Let us study for a while optimization techniques for minimizing large sums of functions

$$
\min _{\mathbf{w} \in \mathbb{R}^{d}} \frac{1}{n} \sum_{i=1}^{n} f_{i}(\mathbf{w}) .
$$

Good candidates are

- stochastic optimization techniques;
- randomized incremental optimization techniques;

We will see a couple of such algorithms with their convergence rates and start with the (batch) gradient descent method.

## Introduction of a few optimization principles

Why do we care about convexity?

## Introduction of a few optimization principles

Why do we care about convexity?
Local observations give information about the global optimum

- $\nabla f(\mathbf{w})=0$ is a necessary and sufficient optimality condition for differentiable convex functions;
- it is often easy to upper-bound $f(\mathbf{w})-f^{\star}$.

## Introduction of a few optimization principles

An important inequality for smooth convex functions
If $f$ is convex

- $f(\mathbf{w}) \geq \underbrace{f\left(\mathbf{w}^{0}\right)+\nabla f\left(\mathbf{w}^{0}\right)^{\top}\left(\mathbf{w}-\mathbf{w}^{0}\right)}_{\text {linear approximation }} ;$
- this is an equivalent definition of convexity for smooth functions.

## Introduction of a few optimization principles

An important inequality for smooth functions
If $\nabla f$ is L-Lipschitz continuous ( $f$ does not need to be convex)

- $f(\mathbf{w}) \leq g(\mathbf{w})=f\left(\mathbf{w}^{0}\right)+\nabla f\left(\mathbf{w}^{0}\right)^{\top}\left(\mathbf{w}-\mathbf{w}^{0}\right)+\frac{L}{2}\left\|\mathbf{w}-\mathbf{w}^{0}\right\|_{2}^{2}$;
- $g(\mathbf{w})=C_{\mathbf{w}^{0}}+\frac{L}{2}\left\|\mathbf{w}^{0}-(1 / L) \nabla f\left(\mathbf{w}^{0}\right)-\mathbf{w}\right\|_{2}^{2}$.

## Introduction of a few optimization principles

An important inequality for smooth functions
If $\nabla f$ is L-Lipschitz continuous ( $f$ does not need to be convex)

- $f(\mathbf{w}) \leq g(\mathbf{w})=f\left(\mathbf{w}^{0}\right)+\nabla f\left(\mathbf{w}^{0}\right)^{\top}\left(\mathbf{w}-\mathbf{w}^{0}\right)+\frac{L}{2}\left\|\mathbf{w}-\mathbf{w}^{0}\right\|_{2}^{2}$;
- $\mathbf{w}^{1}=\mathbf{w}^{0}-\frac{1}{L} \nabla f\left(\mathbf{w}^{0}\right)$ (gradient descent step).

## Introduction of a few optimization principles

## Gradient Descent Algorithm

Assume that $f$ is convex and differentiable, and that $\nabla f$ is L-Lipschitz.

## Theorem

Consider the algorithm

$$
\mathbf{w}^{t} \leftarrow \mathbf{w}^{t-1}-\frac{1}{L} \nabla f\left(\mathbf{w}^{t-1}\right)
$$

Then,

$$
f\left(\mathbf{w}^{t}\right)-f^{\star} \leq \frac{L\left\|\mathbf{w}^{0}-\mathbf{w}^{\star}\right\|_{2}^{2}}{2 t}
$$

## Remarks

- the convergence rate improves under additional assumptions on $f$ (strong convexity);
- some variants have a $O\left(1 / t^{2}\right)$ convergence rate (Nesterov, 2004).

## Proof (1/2)

Proof of the main inequality for smooth functions
We want to show that for all $\mathbf{w}$ and $\mathbf{z}$,

$$
f(\mathbf{w}) \leq f(\mathbf{z})+\nabla f(\mathbf{z})^{\top}(\mathbf{w}-\mathbf{z})+\frac{L}{2}\|\mathbf{w}-\mathbf{z}\|_{2}^{2}
$$

## Proof (1/2)

## Proof of the main inequality for smooth functions

We want to show that for all $\mathbf{w}$ and $\mathbf{z}$,

$$
f(\mathbf{w}) \leq f(\mathbf{z})+\nabla f(\mathbf{z})^{\top}(\mathbf{w}-\mathbf{z})+\frac{L}{2}\|\mathbf{w}-\mathbf{z}\|_{2}^{2}
$$

By using Taylor's theorem with integral form,

$$
f(\mathbf{w})-f(\mathbf{z})=\int_{0}^{1} \nabla f(t \mathbf{w}+(1-t) \mathbf{z})^{\top}(\mathbf{w}-\mathbf{z}) d t
$$

Then,

$$
\begin{aligned}
f(\mathbf{w})-f(\mathbf{z})-\nabla f(\mathbf{z})^{\top}(\mathbf{w}-\mathbf{z}) & \leq \int_{0}^{1}(\nabla f(t \mathbf{w}+(1-t) \mathbf{z})-\nabla f(\mathbf{z}))^{\top}(\mathbf{w}-\mathbf{z}) d t \\
& \leq \int_{0}^{1}\left|(\nabla f(t \mathbf{w}+(1-t) \mathbf{z})-\nabla f(\mathbf{z}))^{\top}(\mathbf{w}-\mathbf{z})\right| d t \\
& \leq \int_{0}^{1}\|\nabla f(t \mathbf{w}+(1-t) \mathbf{z})-\nabla f(\mathbf{z})\|_{2}\|\mathbf{w}-\mathbf{z}\|_{2} d t \quad \text { (C.-S.) } \\
& \leq \int_{0}^{1} L t\|\mathbf{w}-\mathbf{z}\|_{2}^{2} d t=\frac{L}{2}\|\mathbf{w}-\mathbf{z}\|_{2}^{2}
\end{aligned}
$$

## Proof (2/2)

## Proof of the theorem

We have shown that for all $\mathbf{w}$,

$$
f(\mathbf{w}) \leq g_{t}(\mathbf{w})=f\left(\mathbf{w}^{t-1}\right)+\nabla f\left(\mathbf{w}^{t-1}\right)^{\top}\left(\mathbf{w}-\mathbf{w}^{t-1}\right)+\frac{L}{2}\left\|\mathbf{w}-\mathbf{w}^{t-1}\right\|_{2}^{2}
$$

$g_{t}$ is minimized by $\mathbf{w}^{t}$; it can be rewritten $g_{t}(\mathbf{w})=g_{t}\left(\mathbf{w}^{t}\right)+\frac{L}{2}\left\|\mathbf{w}-\mathbf{w}^{t}\right\|_{2}^{2}$. Then,

$$
\begin{aligned}
f\left(\mathbf{w}^{t}\right) & \leq g_{t}\left(\mathbf{w}^{t}\right)=g_{t}\left(\mathbf{w}^{\star}\right)-\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t}\right\|_{2}^{2} \\
& =f\left(\mathbf{w}^{t-1}\right)+\nabla f\left(\mathbf{w}^{t-1}\right)^{\top}\left(\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right)+\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right\|_{2}^{2}-\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t}\right\|_{2}^{2} \\
& \leq f^{\star}+\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right\|_{2}^{2}-\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t}\right\|_{2}^{2} .
\end{aligned}
$$

By summing from $t=1$ to $T$, we have a telescopic sum

$$
T\left(f\left(\mathbf{w}^{T}\right)-f^{\star}\right) \leq \sum_{t=1}^{T} f\left(\mathbf{w}^{t}\right)-f^{\star} \leq \frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{0}\right\|_{2}^{2}-\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{T}\right\|_{2}^{2}
$$

## Introduction of a few optimization principles

An important inequality for smooth and $\mu$-strongly convex functions
If $\nabla f$ is L-Lipschitz continuous and $f \mu$-strongly convex

- $f(\mathbf{w}) \leq f\left(\mathbf{w}^{0}\right)+\nabla f\left(\mathbf{w}^{0}\right)^{\top}\left(\mathbf{w}-\mathbf{w}^{0}\right)+\frac{L}{2}\left\|\mathbf{w}-\mathbf{w}^{0}\right\|_{2}^{2} ;$
- $f(\mathbf{w}) \geq f\left(\mathbf{w}^{0}\right)+\nabla f\left(\mathbf{w}^{0}\right)^{\top}\left(\mathbf{w}-\mathbf{w}^{0}\right)+\frac{\mu}{2}\left\|\mathbf{w}-\mathbf{w}^{0}\right\|_{2}^{2}$;

## Introduction of a few optimization principles

## Proposition

When $f$ is $\mu$-strongly convex, differentiable and $\nabla f$ is $L$-Lipschitz, the gradient descent algorithm with step-size $1 / L$ produces iterates such that

$$
f\left(\mathbf{w}^{t}\right)-f^{\star} \leq\left(1-\frac{\mu}{L}\right)^{t} \frac{L\left\|\mathbf{w}^{0}-\mathbf{w}^{\star}\right\|_{2}^{2}}{2}
$$

We call that a linear convergence rate.

## Proof

We start from an inequality from the previous proof

$$
\begin{aligned}
f\left(\mathbf{w}^{t}\right) & \leq f\left(\mathbf{w}^{t-1}\right)+\nabla f\left(\mathbf{w}^{t-1}\right)^{\top}\left(\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right)+\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right\|_{2}^{2}-\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t}\right\|_{2}^{2} \\
& \leq f^{\star}+\frac{L-\mu}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right\|_{2}^{2}-\frac{L}{2}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t}\right\|_{2}^{2}
\end{aligned}
$$

In addition, we have that $f\left(\mathbf{w}^{t}\right) \geq f^{\star}+\frac{\mu}{2}\left\|\mathbf{w}^{t}-\mathbf{w}^{\star}\right\|_{2}^{2}$, and thus

$$
\begin{aligned}
\left\|\mathbf{w}^{\star}-\mathbf{w}^{t}\right\|_{2}^{2} & \leq \frac{L-\mu}{L+\mu}\left\|\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right\|_{2}^{2} \\
& \leq\left(1-\frac{\mu}{L}\right)\left\|\mathbf{w}^{\star}-\mathbf{w}^{t-1}\right\|_{2}^{2} .
\end{aligned}
$$

Finally,

$$
\begin{aligned}
f\left(\mathbf{w}^{t}\right)-f^{\star} & \leq \frac{L}{2}\left\|\mathbf{w}^{t}-\mathbf{w}^{\star}\right\|_{2}^{2} \\
& \leq\left(1-\frac{\mu}{L}\right)^{t} \frac{L\left\|\mathbf{w}^{\star}-\mathbf{w}^{0}\right\|_{2}^{2}}{2}
\end{aligned}
$$

## The stochastic (sub)gradient descent algorithm

Consider now the minimization of an expectation

$$
\min _{\mathbf{w} \in \mathbb{R}^{p}} f(\mathbf{w})=\mathbb{E}_{\mathbf{x}}[\ell(\mathbf{x}, \mathbf{w})]
$$

To simplify, we assume that for all $\mathbf{x}, \mathbf{w} \mapsto \ell(\mathbf{x}, \mathbf{w})$ is differentiable, but everything here is true for nonsmooth functions.

## Algorithm

At iteration $t$,

- Randomly draw one example $\mathbf{x}_{t}$ from the training set;
- Update the current iterate

$$
\mathbf{w}^{t} \leftarrow \mathbf{w}^{t-1}-\eta_{t} \nabla_{\mathbf{w}} \ell\left(\mathbf{x}_{t}, \mathbf{w}_{t-1}\right)
$$

- Perform online averaging of the iterates (optional)

$$
\tilde{\mathbf{w}}^{t} \leftarrow\left(1-\gamma_{t}\right) \tilde{\mathbf{w}}^{t-1}+\gamma_{t} \mathbf{w}^{t}
$$

## The stochastic (sub)gradient descent algorithm

There are various learning rates strategies (constant, varying step-sizes), and averaging strategies. Depending on the problem assumptions and choice of $\eta_{t}, \gamma_{t}$, classical convergence rates may be obtained:

- $f\left(\tilde{\mathbf{w}}^{t}\right)-f^{\star}=O(1 / \sqrt{t})$ for convex problems;
- $f\left(\tilde{\mathbf{w}}^{t}\right)-f^{\star}=O(1 / t)$ for strongly-convex ones;

## Remarks

- The convergence rates are not that great, but the complexity per-iteration is small (1 gradient evaluation for minimizing an empirical risk versus $n$ for the batch algorithm).
- When the amount of data is infinite, the method minimizes the expected risk.
- Choosing a good learning rate automatically is an open problem.

## Randomized incremental algorithms $(1 / 2)$

Consider now the minimization of a large finite sum of smooth convex functions:

$$
\min _{\mathbf{w} \in \mathbb{R}^{p}} \frac{1}{n} \sum_{i=1}^{n} f_{i}(\mathbf{w})
$$

A class of algorithms with low per-iteration complexity have been recently introduced that enjoy exponential (aka, linear) convergence rates for strongly-convex problems, e.g., SAG (Schmidt et al., 2016).

SAG algorithm

$$
\mathbf{w}^{t} \leftarrow \mathbf{w}^{t-1}-\frac{\gamma}{L n} \sum_{i=1}^{n} \mathbf{y}_{i}^{t} \text { with } \mathbf{y}_{i}^{t}=\left\{\begin{array}{cl}
\nabla f_{i}\left(\mathbf{w}^{t-1}\right) & \text { if } i=i_{t} \\
\mathbf{y}_{i}^{t-1} & \text { otherwise }
\end{array}\right.
$$

See also SAGA (Defazio et al., 2014), SVRG (Xiao and Zhang, 2014), SDCA (Shalev-Shwartz and Zhang, 2015), MISO (Mairal, 2015);

## Randomized incremental algorithms (2/2)

Many of these techniques are in fact performing SGD-types of steps

$$
\mathbf{w}^{t} \leftarrow \mathbf{w}^{t-1}-\eta_{t} \mathbf{g}_{t}
$$

where $\mathbb{E}\left[\mathbf{g}_{t} \mid \mathbf{w}_{t-1}\right]=\nabla f\left(\mathbf{w}_{t-1}\right)$, but where the estimator of the gradient has lower variance than in SGD, see SVRG (Xiao and Zhang, 2014).
Typically, these methods have the convergence rate

$$
f\left(\mathbf{w}_{t}\right)-f^{\star}=O\left(\left(1-C \max \left(\frac{1}{n}, \frac{\mu}{L}\right)\right)^{t}\right)
$$

## Remarks

- their complexity per-iteration is independent of $n$ !
- unlike SGD, they are often almost parameter-free.
- besides, they can be accelerated (Lin et al., 2015).

## Large-scale learning with linear models

## Conclusion

- we know how to deal with huge-scale linear problems;
- this is also useful to learn with kernels!

## Outline

(6) Open Problems and Research Topics

- Multiple Kernel Learning (MKL)
- Large-scale learning with kernels
- Motivation
- Interlude: Large-scale learning with linear models
- Nyström approximations
- Random Fourier features
- Foundations of deep learning from a kernel point of view

## Nyström approximations: principle

Consider a p.d. kernel $K: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ and RKHS $\mathcal{H}$, with the mapping $\varphi: \mathcal{X} \rightarrow \mathcal{H}$ such that

$$
K\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\left\langle\varphi(\mathbf{x}), \varphi\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}} .
$$

The Nyström method consists of replacing any point $\varphi(\mathbf{x})$ in $\mathcal{H}$, for $\mathbf{x}$ in $\mathcal{X}$ by its orthogonal projection onto a finite-dimensional subspace

$$
\mathcal{F}:=\operatorname{Span}\left(f_{1}, \ldots, f_{p}\right) \quad \text { with } p \ll n,
$$

where the $f_{i}$ 's are anchor points in $\mathcal{H}$ (to be defined later).

## Motivation

- This principle allows us to work explicitly in a finite-dimensional space; it was introduced several times in the kernel literature [Williams and Seeger, 2002], [Smola and Schölkopf, 2000], [Fine and Scheinberg, 2001].

## Nyström approximations: principle

The orthogonal projection is defined as

$$
\Pi_{\mathcal{F}}[\mathbf{x}]:=\underset{f \in \mathcal{F}}{\operatorname{argmin}}\|\varphi(\mathbf{x})-f\|_{\mathcal{H}}^{2}
$$

## Nyström approximations: principle

The projection is equivalent to

$$
\Pi_{\mathcal{F}}[\mathbf{x}]:=\sum_{j=1}^{p} \beta_{j}^{\star} f_{j} \quad \text { with } \quad \boldsymbol{\beta}^{\star} \in \underset{\boldsymbol{\beta} \in \mathbb{R}^{p}}{\operatorname{argmin}}\left\|\varphi(\mathbf{x})-\sum_{j=1}^{p} \beta_{j} f_{j}\right\|_{\mathcal{H}}^{2}
$$

and $\boldsymbol{\beta}^{\star}$ is the solution of the problem

$$
\min _{\boldsymbol{\beta} \in \mathbb{R}^{p}}-2 \sum_{j=1}^{p} \beta_{j}\left\langle f_{j}, \varphi(\mathbf{x})\right\rangle_{\mathcal{H}}+\sum_{j, l=1}^{p} \beta_{j} \beta_{l}\left\langle f_{j}, f_{l}\right\rangle_{\mathcal{H}},
$$

or also

$$
\min _{\boldsymbol{\beta} \in \mathbb{R}^{p}}-2 \sum_{j=1}^{p} \beta_{j} f_{j}(\mathbf{x})+\sum_{j, l=1}^{p} \beta_{j} \beta_{l}\left\langle f_{j}, f_{l}\right\rangle_{\mathcal{H}} .
$$

## Nyström approximations: principle

Then, call $\left[\mathbf{K}_{\mathbf{f}}\right]_{j l}=\left\langle f_{j}, f_{l}\right\rangle_{\mathcal{H}}$ and $\mathbf{f}(\mathbf{x})=\left[f_{1}(\mathbf{x}), \ldots, f_{p}(\mathbf{x})\right]$ in $\mathbb{R}^{p}$. The problem may be rewritten as

$$
\min _{\boldsymbol{\beta} \in \mathbb{R}^{p}}-2 \boldsymbol{\beta}^{\top} \mathbf{f}(\mathbf{x})+\boldsymbol{\beta}^{\top} \mathbf{K}_{\mathbf{f}} \boldsymbol{\beta}
$$

and, assuming $\mathbf{K}_{\mathbf{f}}$ to be non-singular for simplicity, the solution is $\boldsymbol{\beta}^{\star}(\mathbf{x})=\mathbf{K}_{\mathbf{f}}^{-1} \mathbf{f}(\mathbf{x})$. Then,

$$
\varphi(\mathbf{x}) \approx \sum_{j=1}^{p} \beta_{j}^{\star}(\mathbf{x}) f_{j}
$$

and

$$
\begin{aligned}
\left\langle\varphi(\mathbf{x}), \varphi\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathcal{H}} & \approx\left\langle\sum_{j=1}^{p} \beta_{j}^{\star}(\mathbf{x}) f_{j}, \sum_{j=1}^{p} \beta_{j}^{\star}\left(\mathbf{x}^{\prime}\right) f_{j}\right\rangle_{\mathcal{H}} \\
& =\sum_{j, l=1}^{p} \beta_{j}^{\star}(\mathbf{x}) \beta_{l}^{\star}\left(\mathbf{x}^{\prime}\right)\left\langle f_{j}, f_{l}\right\rangle_{\mathcal{H}}=\boldsymbol{\beta}^{\star}(\mathbf{x})^{\top} \mathbf{K}_{\mathbf{f}} \boldsymbol{\beta}^{\star}\left(\mathbf{x}^{\prime}\right) .
\end{aligned}
$$

## Nyström approximations: principle

This allows us to define the mapping

$$
\psi(\mathbf{x})=\mathbf{K}_{\mathbf{f}}^{1 / 2} \boldsymbol{\beta}^{\star}(\mathbf{x})=\mathbf{K}_{\mathbf{f}}^{-1 / 2} \mathbf{f}(\mathbf{x})
$$

and we have the approximation $K\left(\mathbf{x}, \mathbf{x}^{\prime}\right) \approx\left\langle\psi(\mathbf{x}), \psi\left(\mathbf{x}^{\prime}\right)\right\rangle_{\mathbb{R}^{p}}$.

## Remarks

- the mapping provides low-rank approximations of the kernel matrix. Given an $n \times n$ Gram matrix $\mathbf{K}$ computed on a training set $\mathcal{S}=\left\{\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right\}$, we have

$$
\mathbf{K} \approx \psi(\mathcal{S})^{\top} \psi(\mathcal{S})
$$

where $\psi(\mathcal{S}):=\left[\psi\left(\mathbf{x}_{1}\right), \ldots, \psi\left(\mathbf{x}_{n}\right)\right]$.

- the approximation has a geometric interpretation.
- We need to define a good strategy for choosing the $f_{j}$ 's.

## Nyström approximation via kernel PCA

Let us now try to learn the $f_{j}$ 's given training data $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathcal{X}$ :

$$
\min _{\substack{f_{1}, \ldots, f_{p} \in \mathcal{H} \\ \beta_{i j} \in \mathbb{R}}} \sum_{i=1}^{n}\left\|\varphi\left(\mathbf{x}_{i}\right)-\sum_{j=1}^{p} \beta_{i j} f_{j}\right\|_{\mathcal{H}}^{2}
$$

Using similar calculation as before, the objective is equivalent to

$$
\min _{\substack{f_{1}, \ldots, f_{p} \in \mathcal{H} \\ \boldsymbol{\beta}_{i} \in \mathbb{R}^{\mathcal{P}}}} \sum_{i=1}^{n}-2 \boldsymbol{\beta}_{i}^{\top} \mathbf{f}\left(\mathbf{x}_{i}\right)+\boldsymbol{\beta}_{i}^{\top} \mathbf{K}_{\mathbf{f}} \boldsymbol{\beta}_{i}
$$

and, by minimizing with respect to all $\boldsymbol{\beta}_{\boldsymbol{i}}$ with $\mathbf{f}$ fixed, we have that $\boldsymbol{\beta}_{\boldsymbol{i}}=\mathbf{K}_{\mathbf{f}}^{-1} \mathbf{f}\left(\mathbf{x}_{i}\right)$ (assuming $\mathbf{K}_{\mathbf{f}}$ to be invertible), which leads to

$$
\max _{f_{1}, \ldots, f_{p} \in \mathcal{H}} \sum_{i=1}^{n} \mathbf{f}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{f}}^{-1} \mathbf{f}\left(\mathbf{x}_{i}\right)
$$

## Nyström approximation via kernel PCA

Remember the objective:

$$
\max _{f_{1}, \ldots, f_{p} \in \mathcal{H}} \sum_{i=1}^{n} \mathbf{f}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{f}}^{-1} \mathbf{f}\left(\mathbf{x}_{i}\right)
$$

Consider an optimal solution $\mathbf{f}^{\star}$ and compute the eigenvalue decomposition of $\mathbf{K}_{\mathbf{f}_{\star}}=\mathbf{U} \boldsymbol{\Delta} \mathbf{U}^{\top}$. Then, define the functions

$$
\mathbf{g}^{\star}(\mathbf{x}):=\left[g_{1}^{\star}(\mathbf{x}), \ldots, g_{p}^{\star}(\mathbf{x})\right]=\boldsymbol{\Delta}^{-1 / 2} \mathbf{U}^{\top} \mathbf{f}^{\star}(\mathbf{x}) .
$$

The functions $g_{j}^{\star}$ are points in the RKHS $\mathcal{H}$ since they are linear combinations of the functions $f_{j}^{\star}$ in $\mathcal{H}$.

## Nyström approximation via kernel PCA

Remember the objective:

$$
\max _{f_{1}, \ldots, f_{p} \in \mathcal{H}} \sum_{i=1}^{n} \mathbf{f}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{f}}^{-1} \mathbf{f}\left(\mathbf{x}_{i}\right)
$$

Consider an optimal solution $\mathbf{f}^{\star}$ and compute the eigenvalue decomposition of $\mathbf{K}_{\mathbf{f}_{\star}}=\mathbf{U} \boldsymbol{\Delta} \mathbf{U}^{\top}$. Then, define the functions

$$
\mathbf{g}^{\star}(\mathbf{x}):=\left[g_{1}^{\star}(\mathbf{x}), \ldots, g_{p}^{\star}(\mathbf{x})\right]=\mathbf{\Delta}^{-1 / 2} \mathbf{U}^{\top} \mathbf{f}^{\star}(\mathbf{x}) .
$$

The functions $g_{j}^{\star}$ are points in the RKHS $\mathcal{H}$ since they are linear combinations of the functions $f_{j}^{\star}$ in $\mathcal{H}$.

Exercise: check that all we do here and in the next slides can be extended to deal with singular Gram matrices $\mathbf{K}_{\mathbf{f}^{\star}}$ and $\mathbf{K}_{\mathbf{f}}$.

## Nyström approximation via kernel PCA

Besides, by construction

$$
\begin{aligned}
{\left[\mathbf{K}_{\mathbf{g}^{\star}}\right]_{j l} } & :=\left\langle g_{j}^{\star}, g_{l}^{\star}\right\rangle_{\mathcal{H}} \\
& =\left\langle\frac{1}{\sqrt{\boldsymbol{\Delta}_{j j}}} \sum_{k=1}^{p}[\mathbf{U}]_{k j} f_{k}^{\star}, \frac{1}{\sqrt{\boldsymbol{\Delta}_{/ /}}} \sum_{k=1}^{p}[\mathbf{U}]_{k l} f_{k}^{\star}\right\rangle_{\mathcal{H}} \\
& =\frac{1}{\sqrt{\mathbf{\Delta}_{j j}}} \frac{1}{\sqrt{\boldsymbol{\Delta}_{/ /}}} \sum_{k, k^{\prime}=1}^{p}[\mathbf{U}]_{k j}[\mathbf{U}]_{k^{\prime} /}\left\langle f_{k}^{\star}, f_{k^{\prime}}^{\star}\right\rangle_{\mathcal{H}} \\
& =\frac{1}{\sqrt{\boldsymbol{\Delta}_{j j}}} \frac{1}{\sqrt{\boldsymbol{\Delta}_{/ /}}} \sum_{k, k^{\prime}=1}^{p}[\mathbf{U}]_{k j}[\mathbf{U}]_{k^{\prime} /}\left[\mathbf{K}_{f \star}\right]_{k k^{\prime}} \\
& =\frac{1}{\sqrt{\mathbf{\Delta}_{j j}}} \frac{1}{\sqrt{\mathbf{\Delta}_{/ /}}} \mathbf{u}_{j}^{\top} \mathbf{K}_{f \star} \mathbf{u}_{/} \\
& =\delta_{j=/ .}
\end{aligned}
$$

## Nyström approximation via kernel PCA

Then, $\mathbf{K}_{\mathbf{g}^{\star}}=\mathbf{I}$ and $\mathbf{g}^{\star}$ is also a solution of the problem

$$
\max _{f_{1}, \ldots, f_{p} \in \mathcal{H}} \sum_{i=1}^{n} \mathbf{f}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{f}}^{-1} \mathbf{f}\left(\mathbf{x}_{i}\right)
$$

since

$$
\begin{aligned}
\mathbf{f}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{f}^{-1}}^{-1} \mathbf{f}^{\star}\left(\mathbf{x}_{i}\right) & =\mathbf{f}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{U} \boldsymbol{\Delta}^{-1} \mathbf{U}^{\top} \mathbf{f}^{\star}\left(\mathbf{x}_{i}\right) \\
& =\mathbf{g}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{g}^{\star}\left(\mathbf{x}_{i}\right)=\mathbf{g}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{g}^{\star}}^{-1} \mathbf{g}^{\star}\left(\mathbf{x}_{i}\right),
\end{aligned}
$$

and also a solution of the problem

$$
\max _{g_{1}, \ldots, g_{\rho} \in \mathcal{H}} \sum_{j=1}^{p} \sum_{i=1}^{n} g_{j}\left(\mathbf{x}_{i}\right)^{2} \text { s.t. } g_{j} \perp g_{k} \text { for } k \neq j \text { and }\left\|g_{j}\right\|_{\mathcal{H}}=1 .
$$

## Nyström approximation via kernel PCA

Then, $\mathbf{K}_{\mathbf{g}^{\star}}=\mathbf{I}$ and $\mathbf{g}^{\star}$ is also a solution of the problem

$$
\max _{f_{1}, \ldots, f_{p} \in \mathcal{H}} \sum_{i=1}^{n} \mathbf{f}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{f}}^{-1} \mathbf{f}\left(\mathbf{x}_{i}\right)
$$

since

$$
\begin{aligned}
\mathbf{f}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{f}^{\star}}^{-1} \mathbf{f}^{\star}\left(\mathbf{x}_{i}\right) & =\mathbf{f}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{U} \Delta^{-1} \mathbf{U}^{\top} \mathbf{f}^{\star}\left(\mathbf{x}_{i}\right) \\
& =\mathbf{g}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{g}^{\star}\left(\mathbf{x}_{i}\right)=\mathbf{g}^{\star}\left(\mathbf{x}_{i}\right)^{\top} \mathbf{K}_{\mathbf{g}^{\star}}^{-1} \mathbf{g}^{\star}\left(\mathbf{x}_{i}\right),
\end{aligned}
$$

and also a solution of the problem

$$
\max _{g_{1}, \ldots, g_{p} \in \mathcal{H}} \sum_{j=1}^{p} \sum_{i=1}^{n} g_{j}\left(\mathbf{x}_{i}\right)^{2} \text { s.t. } g_{j} \perp g_{k} \text { for } k \neq j \text { and }\left\|g_{j}\right\|_{\mathcal{H}}=1
$$

This is the kernel PCA formulation!

## Nyström approximation via kernel PCA

## Our first recipe with kernel PCA

Given a dataset of $n$ training points $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathcal{X}$,

- randomly choose a subset $\mathcal{Z}=\left[\mathbf{x}_{z_{1}}, \ldots, \mathbf{x}_{z_{m}}\right]$ of $m \leq n$ training points;
- compute the $m \times m$ kernel matrix $\mathbf{K}_{\mathcal{Z}}$.
- perform kernel PCA to find the $p \leq m$ largest principal directions (parametrized by $p$ vectors $\alpha_{j}$ in $\mathbb{R}^{m}$ );
Then, every point $\mathbf{x}$ in $\mathcal{X}$ may be approximated by

$$
\begin{aligned}
\psi(\mathbf{x}) & =\mathbf{K}_{\mathbf{g}_{\star}}^{-1 / 2} \mathbf{g}^{\star}(\mathbf{x})=\mathbf{g}^{\star}(\mathbf{x})=\left[g_{1}^{\star}(\mathbf{x}), \ldots, g_{p}^{\star}(\mathbf{x})\right]^{\top} \\
& =\left[\sum_{i=1}^{m} \alpha_{1 i} K\left(\mathbf{x}_{z_{i}}, \mathbf{x}\right), \ldots, \sum_{i=1}^{m} \alpha_{p i} K\left(\mathbf{x}_{z_{i}}, \mathbf{x}\right)\right]^{\top}
\end{aligned}
$$

## Nyström approximation via kernel PCA

## Remarks

- The vector $\psi(\mathbf{x})$ can be interpreted as coordinates of the projection of $\varphi(\mathbf{x})$ onto the (orthogonal) PCA basis.
- The complexity of training is $O\left(m^{3}\right)$ (eig decomposition of $\left.\mathbf{K}_{\mathcal{Z}}\right)+$ $O\left(m^{2}\right)$ kernel evaluations.
- The complexity of encoding a new point $\mathbf{x}$ is $O(m p)$ (matrix vector multiplication) $+O(m)$ kernel evaluations.

## Nyström approximation via kernel PCA

## Remarks

- The vector $\psi(\mathbf{x})$ can be interpreted as coordinates of the projection of $\varphi(\mathbf{x})$ onto the (orthogonal) PCA basis.
- The complexity of training is $O\left(m^{3}\right)$ (eig decomposition of $\left.\mathbf{K}_{\mathcal{Z}}\right)+$ $O\left(m^{2}\right)$ kernel evaluations.
- The complexity of encoding a new point $\mathbf{x}$ is $O(m p)$ (matrix vector multiplication) $+O(m)$ kernel evaluations.

The main issue is the encoding time, which depends linearly on $m>p$.

## Nyström approximation via random sampling

A popular alternative is instead to select the anchor points among the training data points $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$-that is,

$$
\mathcal{F}:=\operatorname{span}\left(\varphi\left(\mathbf{x}_{z_{1}}\right), \ldots, \varphi\left(\mathbf{z}_{z_{p}}\right)\right) .
$$

In other words, choose $f_{1}=\varphi\left(\mathbf{x}_{z_{1}}\right), \ldots, f_{p}=\varphi\left(\mathbf{x}_{z_{p}}\right)$.

## Second recipe with random point sampling

Given a dataset of $n$ training points $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$ in $\mathcal{X}$,

- randomly choose a subset $\mathcal{Z}=\left[\mathrm{x}_{z_{1}}, \ldots, \mathbf{x}_{z_{p}}\right]$ of $p$ training points;
- compute the $p \times p$ kernel matrix $\mathbf{K}_{\mathcal{Z}}$.

Then, a new point $\mathbf{x}$ is encoded as

$$
\begin{aligned}
\psi(\mathbf{x}) & =\mathbf{K}_{\mathcal{Z}}^{-1 / 2} \mathbf{f}_{\mathcal{Z}}(\mathbf{x}) \\
& =\mathbf{K}_{\mathcal{Z}}^{-1 / 2}\left[K\left(\mathbf{x}_{z_{1}}, \mathbf{x}\right), \ldots, K\left(\mathbf{x}_{z_{p}}, \mathbf{x}\right)\right]^{\top}
\end{aligned}
$$

## Nyström approximation via random sampling

- The complexity of training is $O\left(p^{3}\right)$ (eig decomposition) $+O\left(p^{2}\right)$ kernel evaluations.
- The complexity of encoding a point $\mathbf{x}$ is $O\left(p^{2}\right)$ (matrix vector multiplication) $+O(p)$ kernel evaluations.

## Nyström approximation via random sampling

- The complexity of training is $O\left(p^{3}\right)$ (eig decomposition) $+O\left(p^{2}\right)$ kernel evaluations.
- The complexity of encoding a point $\mathbf{x}$ is $O\left(p^{2}\right)$ (matrix vector multiplication) $+O(p)$ kernel evaluations.
The main issue complexity is better, but we lose the "optimality" of the PCA basis and the random choice of anchor points is not clever.

## Nyström approximation via greedy approach

Better approximation can be obtained with a greedy algorithm that iteratively selects one column at a time with largest residual (Bach and Jordan, 2002; Smola and Shölkopf, 2000, Fine and Scheinbert, 2000).

At iteration $k$, assume that $\mathcal{Z}=\left\{\mathbf{x}_{z_{1}}, \ldots, \mathbf{x}_{z_{k}}\right\}$; then, the residual for a data point $\mathbf{x}$ encoded with $k$ anchor points $f_{1}, \ldots, f_{k}$ is

$$
\min _{\boldsymbol{\beta} \in \mathbb{R}^{k}}\left\|\varphi(\mathbf{x})-\sum_{j=1}^{k} \beta_{j} \varphi\left(\mathbf{x}_{z_{j}}\right)\right\|_{\mathcal{H}}^{2}
$$

which is equal to

$$
\|\varphi(\mathbf{x})\|_{\mathcal{H}}^{2}-\mathbf{f}_{\mathcal{Z}}(\mathbf{x})^{\top} \mathbf{K}_{\mathcal{Z}}^{-1} \mathbf{f}_{\mathcal{Z}}(\mathbf{x})
$$

and since $f_{j}=\varphi\left(\mathbf{x}_{z_{j}}\right)$ for all $j$, the data point $\mathbf{x}_{i}$ with largest residual is the one that maximizes

$$
K\left(\mathbf{x}_{i}, \mathbf{x}_{i}\right)-\mathbf{f}_{\mathcal{Z}}\left(\mathbf{x}_{i}\right) \mathbf{K}_{\mathcal{Z}}^{-1} \mathbf{f}_{\mathcal{Z}}\left(\mathbf{x}_{i}\right) \text { with } \mathbf{f}_{\mathcal{Z}}\left(\mathbf{x}_{i}\right)=\left[K\left(\mathbf{x}_{z_{1}}, \mathbf{x}\right), \ldots, K\left(\mathbf{x}_{z_{k}}, \mathbf{x}\right)\right]^{\top} .
$$

## Nyström approximation via greedy approach

This brings us to the following algorithm
Third recipe with greedy anchor point selection Initialize $Z=\emptyset$. For $k=1, \ldots, p$ do

- data point selection

$$
z_{k} \leftarrow \underset{i \in\{1, \ldots, n\}}{\operatorname{argmax}} K\left(\mathbf{x}_{i}, \mathbf{x}_{i}\right)-\mathbf{f}_{\mathcal{Z}}\left(\mathbf{x}_{i}\right) \mathbf{K}_{\mathcal{Z}}^{-1} \mathbf{f}_{\mathcal{Z}}\left(\mathbf{x}_{i}\right)
$$

- update the set $\mathcal{Z}$

$$
\mathcal{Z} \leftarrow \mathcal{Z} \cup\left\{\mathbf{x}_{z_{k}}\right\}
$$

## Remarks

- A naive implementation costs $\left(O\left(k^{2} n+k^{3}\right)\right.$ at every iteration.
- To get a reasonable complexity, one has to use simple linear algebra tricks (see next slide).

## Nyström approximation via greedy approach

If $\mathcal{Z}^{\prime}=\mathcal{Z} \cup\{\mathbf{z}\}$,

$$
\mathbf{K}_{\mathcal{Z}^{\prime}}^{-1}=\left[\begin{array}{cc}
\mathbf{K}_{\mathcal{Z}} & \mathbf{f}_{\mathcal{Z}}(\mathbf{z}) \\
\mathbf{f}_{\mathcal{Z}}(\mathbf{z})^{\top} & K(\mathbf{z}, \mathbf{z})
\end{array}\right]^{-1}=\left[\begin{array}{cc}
\mathbf{K}_{\mathcal{Z}}^{-1}+\frac{1}{s} \mathbf{b b}^{\top} & -\frac{1}{s} \mathbf{b} \\
-\frac{1}{s} \mathbf{b}^{\top} & \frac{1}{s}
\end{array}\right],
$$

where $s$ is the Schur complement $s=K(\mathbf{z}, \mathbf{z})-\mathbf{f}_{\mathcal{Z}}(\mathbf{z}) \mathbf{K}_{\mathcal{Z}}^{-1} \mathbf{f}_{\mathcal{Z}}(\mathbf{z})$, and $\mathbf{b}=\mathbf{K}_{\mathcal{Z}}^{-1} \mathbf{f}_{\mathcal{Z}}(\mathbf{z})$.

Complexity analysis

- $\mathbf{K}_{\mathcal{Z}^{\prime}}^{-1}$ can be obtained from $\mathbf{K}_{\mathcal{Z}}^{-1}$ and $\mathbf{f}_{\mathcal{Z}}(\mathbf{z})$ in $O\left(k^{2}\right)$ float operations; for that we need to always keep into memory the $n$ vectors $\mathbf{f}_{\mathcal{Z}}\left(\mathbf{x}_{i}\right)$.
- updating the $\mathbf{f}_{\mathcal{Z}^{\prime}}\left(\mathbf{x}_{i}\right)^{\prime}$ 's from $\mathbf{f}_{\mathcal{Z}}\left(\mathbf{x}_{i}\right)$ requires $n$ kernel evaluations; The total training complexity is $O\left(p^{2} n\right)$ float operations and $O(p n)$ kernel evaluations

## Nyström approximation via K-means

When $\mathcal{X}=\mathbb{R}^{d}$, it is also possible to synthesize points $\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}$ such that they represented well some training data $\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}$, leading to the Clustred Nyström approximation (Zhang and Kwok, 2008).

## Fourth recipe with K-means

(1) Perform the regular K-means algorithm on the training data, to obtain $p$ centroids $\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}$ in $\mathbb{R}^{p}$.
(2) Define the anchor points $f_{j}=\varphi\left(\mathbf{z}_{j}\right)$ for $j=1, \ldots, p$, and perform the classical Nyström approximation.

## Remarks

- The complexity is the same as Nyström with random selection (except for the K-means step);
- The method is data-dependent and can significantly outperform the other variants in practice.

## Nyström approximation: conclusion

## Concluding remarks

- The greedy selection rule is equivalent to computing an incomplete Cholesky factorization of the kernel matrix (Bach and Jordan, 2002; Scholköpf and Smola, 2000, Fine and Scheinberg, 2001);
- The techniques we have seen produce low-rank approximations of the kernel matrix $\mathbf{K} \approx \mathbf{L L}^{\top}$;
- The method admits a geometric interpretation in terms of orthogonal projection onto a finite-dimensional subspace.
- The approximation provides points in the RKHS. As such, many operations on the mapping are valid (translations, linear combinations, projections), unlike the method that will come next.

## Random Fourier features [Rahimi and Recht, 2007] (1/5)

A large class of approximations for shift-invariant kernels are based on sampling techniques. Consider a real-valued positive-definite continuous translation-invariant kernel $K(\mathbf{x}, \mathbf{y})=\kappa(\mathbf{x}-\mathbf{y})$ with $\kappa: \mathbb{R}^{d} \rightarrow \mathbb{R}$. Then, if $\kappa(0)=1$, Bochner theorem tells us that $\kappa$ is a valid characteristic function for some probability measure

$$
\kappa(\mathbf{z})=\mathbb{E}_{\mathbf{w}}\left[e^{i \mathbf{w}^{\top} \mathbf{z}}\right] .
$$

Remember indeed that, with the right assumptions on $\kappa$,

$$
\kappa(\mathbf{x}-\mathbf{y})=\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \hat{\kappa}(\mathbf{w}) e^{i \mathbf{w}^{\top} \mathbf{x}} e^{-i \mathbf{w}^{\top} \mathbf{y}} d \mathbf{w}
$$

and the probability measure admits a density $q(\mathbf{w})=\frac{1}{(2 \pi)^{d}} \hat{\kappa}(\mathbf{w})$ (non-negative, real-valued, sum to 1 since $\kappa(0)=1$ ).

## Random Fourier features $(2 / 5)$

Then,

$$
\begin{aligned}
\kappa(\mathbf{x}-\mathbf{y}) & =\frac{1}{(2 \pi)^{d}} \int_{\mathbb{R}^{d}} \hat{\kappa}(\mathbf{w}) e^{i \mathbf{w}^{\top} \mathbf{x}} e^{-i \mathbf{w}^{\top} \mathbf{y}} d \mathbf{w} \\
& =\int_{\mathbb{R}^{d}} q(\mathbf{w}) \cos \left(\mathbf{w}^{\top} \mathbf{x}-\mathbf{w}^{\top} \mathbf{y}\right) d \mathbf{w} \\
& =\int_{\mathbb{R}^{d}} q(\mathbf{w})\left(\cos \left(\mathbf{w}^{\top} \mathbf{x}\right) \cos \left(\mathbf{w}^{\top} \mathbf{y}\right)+\sin \left(\mathbf{w}^{\top} \mathbf{x}\right) \sin \left(\mathbf{w}^{\top} \mathbf{y}\right)\right) d \mathbf{w} \\
& =\int_{\mathbb{R}^{d}} \int_{b=0}^{2 \pi} \frac{q(\mathbf{w})}{2 \pi} 2 \cos \left(\mathbf{w}^{\top} \mathbf{x}+b\right) \cos \left(\mathbf{w}^{\top} \mathbf{y}+b\right) d \mathbf{w} d b \quad \text { (exercise) } \\
& =\mathbb{E}_{\mathbf{w} \sim q(\mathbf{w}), b \sim \mathcal{U}[0,2 \pi]}\left[\sqrt{2} \cos \left(\mathbf{w}^{\top} \mathbf{x}+b\right) \sqrt{2} \cos \left(\mathbf{w}^{\top} \mathbf{y}+b\right)\right]
\end{aligned}
$$

## Random Fourier features $(3 / 5)$

## Random Fourier features recipe

- Compute the Fourier transform of the kernel $\hat{\kappa}$ and define the probability density $q(\mathbf{w})=\hat{\kappa}(\mathbf{w}) /(2 \pi)^{d}$;
- Draw $p$ i.i.d. samples $\mathbf{w}_{1}, \ldots, \mathbf{w}_{p}$ from $q$ and $p$ i.i.d. samples $b_{1}, \ldots, b_{p}$ from the uniform distribution on $[0,2 \pi]$;
- define the mapping

$$
\mathbf{x} \mapsto \psi(\mathbf{x})=\sqrt{\frac{2}{d}}\left[\cos \left(\mathbf{w}_{1}^{\top} \mathbf{x}+b_{1}\right), \ldots, \cos \left(\mathbf{w}_{p}^{\top} \mathbf{x}+b_{p}\right)\right]^{\top} .
$$

Then, we have that

$$
\kappa(\mathbf{x}-\mathbf{y}) \approx\langle\psi(\mathbf{x}), \psi(\mathbf{y})\rangle_{\mathbb{R}^{p}}
$$

The two quantities are equal in expectation.

## Random Fourier features $(4 / 5)$

Theorem, [Rahimi and Recht, 2007]
On any compact subset $\mathcal{X}$ of $\mathbb{R}^{m}$, for all $\varepsilon>0$,
$\mathbb{P}\left[\sup _{x, y \in \mathcal{X}}\left|\kappa(\mathbf{x}-\mathbf{y})-\langle\psi(\mathbf{x}), \psi(\mathbf{y})\rangle_{\mathbb{R}^{p}}\right| \geq \varepsilon\right] \leq 2^{8}\left(\frac{\sigma_{q} \operatorname{diam}(\mathcal{X})}{\varepsilon}\right)^{2} e^{-\frac{\rho^{2}}{4(m+2)}}$,
where $\sigma_{q}^{2}=\mathbb{E}_{\mathbf{w} \sim q(\mathbf{w})}\left[\mathbf{w}^{\top} \mathbf{w}\right]$ is the second moment of the Fourier transform of $\kappa$.

## Remarks

- The convergence is uniform, not data dependent;
- Take the sequence $\varepsilon_{p}=\sqrt{\frac{\log (p)}{p}} \sigma_{q} \operatorname{diam}(\mathcal{X})$; Then the term on the right converges to zero when $p$ grows to infinity;
- Prediction functions with Random Fourier features are not in $\mathcal{H}$.

## Random Fourier features $(5 / 5)$

## Ingredients of the proof

- For a fixed pair of points $\mathbf{x}, \mathbf{y}$, Hoeffding's inequality says that

$$
\mathbb{P}[\underbrace{\left|\kappa(\mathbf{x}-\mathbf{y})-\langle\psi(\mathbf{x}), \psi(\mathbf{y})\rangle_{\mathbb{R}^{d}}\right|}_{f(x, y)} \geq \varepsilon] \leq 2 e^{-\frac{\rho^{2}}{4}} .
$$

- Consider a net (set of balls of radius $r$ ) that covers $\mathcal{X}_{\Delta}=\{\mathbf{x}-\mathbf{y}:(\mathbf{x}, \mathbf{y}) \in \mathcal{X}\}$ with at most $T=(4 \operatorname{diam}(\mathcal{X}) / r)^{m}$ balls.
- Apply the Hoeffding's inequality to the centers $\mathbf{x}_{i}-\mathbf{y}_{i}$ of the balls;
- Use a basic union bound

$$
\mathbb{P}\left[\sup _{i} f\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right) \geq \frac{\varepsilon}{2}\right] \leq \sum_{i} \mathbb{P}\left[f\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right) \geq \frac{\varepsilon}{2}\right] \leq 2 T e^{-\frac{\rho \varepsilon^{2}}{8}}
$$

- Glue things together: control the probability for points ( $\mathbf{x}, \mathbf{y}$ ) inside each ball, and adjust the radius $r$ (a bit technical).

## In the context of supervised learning

The goal is to learn a prediction function $f: \mathcal{X} \rightarrow \mathcal{Y}$ given labeled training data $\left(x_{i}, y_{i}\right)_{i=1, \ldots, n}$ with $x_{i}$ in $\mathcal{X}$, and $y_{i}$ in $\mathcal{Y}$ :

$$
\min _{f \in \mathcal{F}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(x_{i}\right)\right)}_{\text {empirical risk, data fit }}+\underbrace{\lambda \Omega(f)}_{\text {regularization }}
$$

What is specific to multilayer neural networks?

- The "neural network" space $\mathcal{F}$ is explicitly parametrized by:

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)
$$

- Linear operations are either unconstrained (fully connected) or involve parameter sharing (e.g., convolutions).
- Finding the optimal $\mathbf{A}_{1}, \mathbf{A}_{2}, \ldots, \mathbf{A}_{k}$ yields a non-convex optimization problem.

## Convolutional Neural Networks

Picture from LeCun et al. (1998)

What are the main features of CNNs?

- they capture compositional and multiscale structures in images;
- they provide some invariance;
- they model the local stationarity of images at several scales;

## Convolutional Neural Networks

What are the main features of CNNs?

- they capture compositional and multiscale structures in images;
- they provide some invariance;
- they model the local stationarity of images at several scales;

## CNNs (Picture from unknown source)

ImageNet: 1000 image categories, 10M hand-labeled images; top-5 error rate.

Figure: Top-5 error rate

## Convolutional neural networks for biological sequences

Figure: two-layer CNN architecture from Alipanahi et al. (2015)

- Sequences are represented by one-hot encoding ( $A=(1,0,0,0), C=(0,1,0,0), \ldots)$.
- Single convolution layer followed by linear classifier.

## Convolutional Neural Networks

What are current important problems to solve?
(1) lack of stability and robustness (see next slide).
(2) learning without large amounts of data.
(3) making interpretable decisions.
(1)

## Adversarial examples, Picture from Kurakin et al. (2016)

Figure: Adversarial examples are generated by computer; then printed on paper; a new picture taken on a smartphone fools the classifier.

## Adversarial examples

(b)
clean + noise $\rightarrow$ "ostrich" (Szegedy et al., 2013).

## Adversarial examples

(a real ostrich)

## Adversarial examples

## adversarial perturbation

88\% tabby cat
99\% guacamole

## Convolutional Neural Networks

$$
\min _{f \in \mathcal{F}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)}_{\text {empirical risk, data fit }}+\underbrace{\lambda \Omega(f)}_{\text {regularization }}
$$

The issue of regularization

- today, heuristics are used (DropOut, weight decay, early stopping)...
- ...but they are not sufficient.
- how to control variations of prediction functions?

$$
\left|f(\mathbf{x})-f\left(\mathbf{x}^{\prime}\right)\right| \text { should be close if } \mathbf{x} \text { and } \mathbf{x}^{\prime} \text { are "similar". }
$$

- what does it mean for $x$ and $x^{\prime}$ to be "similar"?
- what should be a good regularization function $\Omega$ ?

## Outline

(6) Open Problems and Research Topics

- Multiple Kernel Learning (MKL)
- Large-scale learning with kernels
- Foundations of deep learning from a kernel point of view
- Motivation
- Deep kernel machines
- Deep learning and stability
- Application to graphs
- Application to biological sequences

## Relevant concepts

- Dot-product kernels:

$$
K\left(x, x^{\prime}\right)=\kappa\left(x^{\top} x^{\prime}\right) \quad \text { or } \quad K\left(x, x^{\prime}\right)=\|x\|\left\|x^{\prime}\right\| \kappa\left(\frac{x^{\top} x^{\prime}}{\|x\|\left\|x^{\prime}\right\|}\right)
$$

- Hierarchical composition of feature spaces:

$$
K\left(x, x^{\prime}\right)=\left\langle\Phi(x), \Phi\left(x^{\prime}\right)\right\rangle \text { with } \Phi(x)=\varphi_{2}\left(\varphi_{1}(x)\right)
$$

- NTK: Asymptotic behavior of over-parametrized deep neural networks learned by gradient descent.
- CKN: Convolutional and hierarchical kernel constructions + end-to-end learning with kernels.

## Relevant concepts

- CKN: Convolutional and hierarchical kernel constructions + end-to-end learning with kernels.
What does it mean to do end-to-end learning with kernels?

## Kernels for deep models: deep kernel machines

Hierarchical kernels (Cho and Saul, 2009b)

- Kernels can be constructed hierarchically

$$
K\left(x, x^{\prime}\right)=\left\langle\Phi(x), \Phi\left(x^{\prime}\right)\right\rangle \text { with } \Phi(x)=\varphi_{2}\left(\varphi_{1}(x)\right)
$$

- e.g., dot-product kernels on the sphere

$$
K\left(x, x^{\prime}\right)=\kappa_{2}\left(\left\langle\varphi_{1}(x), \varphi_{1}\left(x^{\prime}\right)\right\rangle\right)=\kappa_{2}\left(\kappa_{1}\left(x^{\top} x^{\prime}\right)\right)
$$

## Kernels for deep models: deep kernel machines

Hierarchical kernels (Cho and Saul, 2009b)

- Kernels can be constructed hierarchically

$$
K\left(x, x^{\prime}\right)=\left\langle\Phi(x), \Phi\left(x^{\prime}\right)\right\rangle \text { with } \Phi(x)=\varphi_{2}\left(\varphi_{1}(x)\right)
$$

- e.g., dot-product kernels on the sphere

$$
K\left(x, x^{\prime}\right)=\kappa_{2}\left(\left\langle\varphi_{1}(x), \varphi_{1}\left(x^{\prime}\right)\right\rangle\right)=\kappa_{2}\left(\kappa_{1}\left(x^{\top} x^{\prime}\right)\right)
$$

A classical old result (Schoenberg, 1942)
Let $\mathcal{X}=\mathbb{S}$ be the unit sphere of some Hilbert space $\mathcal{H}_{0}$. The kernel $K: \mathcal{X}^{2} \rightarrow \mathbb{R}$

$$
K(\mathbf{x}, \mathbf{y})=\kappa\left(\langle\mathbf{x}, \mathbf{y}\rangle_{\mathcal{H}_{0}}\right),
$$

is positive definite for all $\mathcal{H}_{0}$ if and only if $\kappa$ is smooth and admits an expansion $\kappa(u)=\sum_{i} a_{i} u^{i}$ with non-negative coefficients $a_{i}$.

## Kernels for deep models: dot-product kernels

| linear kernel | $\left\langle z, z^{\prime}\right\rangle$ |
| :--- | :--- |
| exponential kernel | $e^{\alpha\left(\left\langle z, z^{\prime}\right\rangle-1\right)}$ |
| inverse polynomial kernel | $\frac{1}{2-\left\langle z, z^{\prime}\right\rangle}$ |
| polynomial kernel of degree $p$ | $\left(c+\left\langle z, z^{\prime}\right\rangle\right)^{p}$ |
| arc-cosine kernel of degree 1 | $\frac{1}{\pi}(\sin (\theta)+(\pi-\theta) \cos (\theta))$ <br> with $\theta=\arccos \left(\left\langle z, z^{\prime}\right\rangle\right)$ |
| Vovk's kernel of degree 3 | $\frac{1}{3}\left(\frac{1-\left\langle z, z^{\prime}\right\rangle^{3}}{1-\left\langle z, z^{\prime}\right\rangle}\right)=\frac{1}{3}\left(1+\left\langle z, z^{\prime}\right\rangle+\left\langle z, z^{\prime}\right\rangle^{2}\right)$ |

## Kernels for deep models: dot-product kernels

| linear kernel | $\left\langle z, z^{\prime}\right\rangle$ |
| :--- | :--- |
| exponential kernel | $e^{\alpha\left(\left\langle z, z^{\prime}\right\rangle-1\right)}$ |
| inverse polynomial kernel | $\frac{1}{2-\left\langle z, z^{\prime}\right\rangle}$ |
| polynomial kernel of degree $p$ | $\left(c+\left\langle z, z^{\prime}\right\rangle\right)^{p}$ |
| arc-cosine kernel of degree 1 | $\frac{1}{\pi}(\sin (\theta)+(\pi-\theta) \cos (\theta))$ <br> with $\theta=\arccos \left(\left\langle z, z^{\prime}\right\rangle\right)$ |
| Vovk's kernel of degree 3 | $\frac{1}{3}\left(\frac{1-\left\langle z, z^{\prime}\right\rangle^{3}}{1-\left\langle z, z^{\prime}\right\rangle}\right)=\frac{1}{3}\left(1+\left\langle z, z^{\prime}\right\rangle+\left\langle z, z^{\prime}\right\rangle^{2}\right)$ |

## Remark

if $\|z\|=\left\|z^{\prime}\right\|=1$, the exponential kernel recovers the Gaussian kernel

$$
\kappa_{\exp }\left(\left\langle z, z^{\prime}\right\rangle\right)=e^{\alpha\left(\left\langle z, z^{\prime}\right\rangle-1\right)}=e^{-\frac{\alpha}{2}\left\|z-z^{\prime}\right\|^{2}}
$$

## Kernels for deep models: random feature kernels

$$
f_{\theta}(x)=\frac{1}{\sqrt{m}} \sum_{i=1}^{m} v_{i} \sigma\left(w_{i}^{\top} x\right), \quad m \rightarrow \infty
$$

Random feature kernels (RF, Neal, 1996; Rahimi and Recht, 2007)

- $\theta=\left(v_{i}\right)_{i}$, fixed random weights $w_{i} \sim N(0, I)$

$$
K_{R F}(x, y)=\mathbb{E}_{w \sim N(0, l)}\left[\sigma\left(w^{\top} x\right) \sigma\left(w^{\top} y\right)\right]
$$

## Kernels for deep models: random feature kernels

$$
f_{\theta}(x)=\frac{1}{\sqrt{m}} \sum_{i=1}^{m} v_{i} \sigma\left(w_{i}^{\top} x\right), \quad m \rightarrow \infty
$$

Random feature kernels (RF, Neal, 1996; Rahimi and Recht, 2007)

- $\theta=\left(v_{i}\right)_{i}$, fixed random weights $w_{i} \sim N(0, I)$

$$
K_{R F}(x, y)=\mathbb{E}_{w \sim N(0, l)}\left[\sigma\left(w^{\top} x\right) \sigma\left(w^{\top} y\right)\right]
$$

- integral representations are not only available for t.i. kernels. They also work for several dot-product kernels (Cho and Saul, 2009b):

$$
k_{n}(x, y)=\frac{1}{\pi}\|x\|^{n}\|y\|^{n} J_{n}(\theta) \quad \text { with } \quad \theta=\cos ^{-1}\left(\frac{x^{\top} y}{\|x\|\|y\|}\right)
$$

with

$$
J_{n}(\theta)=(-1)^{n}(\sin \theta)^{2 n+1}\left(\frac{1}{\sin \theta} \frac{\partial}{\partial \theta}\right)^{n}\left(\frac{\pi-\theta}{\sin \theta}\right)
$$

## Kernels for deep models: random feature kernels

$$
f_{\theta}(x)=\frac{1}{\sqrt{m}} \sum_{i=1}^{m} v_{i} \sigma\left(w_{i}^{\top} x\right), \quad m \rightarrow \infty
$$

Random feature kernels (RF, Neal, 1996; Rahimi and Recht, 2007)

- $\theta=\left(v_{i}\right)_{i}$, fixed random weights $w_{i} \sim N(0, I)$

$$
K_{R F}(x, y)=\mathbb{E}_{w \sim N(0, l)}\left[\sigma\left(w^{\top} x\right) \sigma\left(w^{\top} y\right)\right]
$$

- integral representations are not only available for t.i. kernels. They also work for several dot-product kernels (Cho and Saul, 2009b):

$$
k_{n}(x, y)=\frac{1}{\pi}\|x\|^{n}\|y\|^{n} J_{n}(\theta) \quad \text { with } \quad \theta=\cos ^{-1}\left(\frac{x^{\top} y}{\|x\|\|y\|}\right)
$$

with

$$
\left\{\begin{array}{l}
J_{0}(\theta)=\pi-\theta \\
J_{1}(\theta)=\sin (\theta)+(\pi-\theta) \cos (\theta) \\
J_{2}(\theta)=3 \sin (\theta) \cos (\theta)+(\pi-\theta)\left(1+2 \cos ^{2}(\theta)\right)
\end{array}\right.
$$

## Kernels for deep models: random feature kernels

Theorem, (Cho and Saul, 2009a)
Consider

$$
k_{n}(x, y)=\frac{1}{\pi}\|x\|^{n}\|y\|^{n} J_{n}(\theta) \quad \text { with } \quad \theta=\cos ^{-1}\left(\frac{x^{\top} y}{\|x\|\|y\|}\right) .
$$

Then

$$
k_{n}(x, y)=\mathbb{E}_{w \sim N(0, l)}\left[\sigma\left(w^{\top} x\right) \sigma\left(w^{\top} y\right)\right]
$$

with $\sigma(u)=\frac{u^{n}}{\sqrt{2}}(1+\operatorname{sign}(u))$.

- Note that $k_{1}(x, y)=\mathbb{E}_{w \sim N(0, l)}\left[\operatorname{RELU}\left(w^{\top} x\right) \operatorname{RELU}\left(w^{\top} y\right)\right]$.
- One of the fundamental tool to analyze RELU networks.

## Kernels for deep models: neural tangent kernels

$$
f_{\theta}(x)=\frac{1}{\sqrt{m}} \sum_{i=1}^{m} v_{i} \sigma\left(w_{i}^{\top} x\right), \quad m \rightarrow \infty
$$

Neural tangent kernels (NTK, Jacot et al., 2018)

- $\theta=\left(v_{i}, w_{i}\right)_{i}$, initialization $\theta_{0} \sim N(0, I)$
- Lazy training (Chizat et al., 2019): $\theta$ stays close to $\theta_{0}$ when training with large $m$

$$
f_{\theta}(x) \approx f_{\theta_{0}}(x)+\left\langle\theta-\theta_{0},\left.\nabla_{\theta} f_{\theta}(x)\right|_{\theta=\theta_{0}}\right\rangle
$$

- Gradient descent for $m \rightarrow \infty \approx$ kernel ridge regression with neural tangent kernel

## Kernels for deep models: neural tangent kernels

$$
f_{\theta}(x)=\frac{1}{\sqrt{m}} \sum_{i=1}^{m} v_{i} \sigma\left(w_{i}^{\top} x\right), \quad m \rightarrow \infty
$$

Neural tangent kernels (NTK, Jacot et al., 2018)

- $\theta=\left(v_{i}, w_{i}\right)_{i}$, initialization $\theta_{0} \sim N(0, I)$
- Lazy training (Chizat et al., 2019): $\theta$ stays close to $\theta_{0}$ when training with large $m$

$$
f_{\theta}(x) \approx f_{\theta_{0}}(x)+\left\langle\theta-\theta_{0},\left.\nabla_{\theta} f_{\theta}(x)\right|_{\theta=\theta_{0}}\right\rangle .
$$

- Gradient descent for $m \rightarrow \infty \approx$ kernel ridge regression with neural tangent kernel

$$
K_{N T K}(x, y)=\lim _{m \rightarrow \infty}\left\langle\nabla_{\theta} f_{\theta_{0}}(x), \nabla_{\theta} f_{\theta_{0}}(y)\right\rangle
$$

## Kernels for deep models: neural tangent kernels

$$
f_{\theta}(x)=\frac{1}{\sqrt{m}} \sum_{i=1}^{m} v_{i} \sigma\left(w_{i}^{\top} x\right), \quad m \rightarrow \infty
$$

Neural tangent kernels (NTK, Jacot et al., 2018)

- $\theta=\left(v_{i}, w_{i}\right)_{i}$, initialization $\theta_{0} \sim N(0, I)$
- Lazy training (Chizat et al., 2019): $\theta$ stays close to $\theta_{0}$ when training with large $m$

$$
f_{\theta}(x) \approx f_{\theta_{0}}(x)+\left\langle\theta-\theta_{0},\left.\nabla_{\theta} f_{\theta}(x)\right|_{\theta=\theta_{0}}\right\rangle .
$$

- Gradient descent for $m \rightarrow \infty \approx$ kernel ridge regression with neural tangent kernel

$$
K_{N T K}(x, y)=\mathbb{E}_{\mathbf{w}}\left[\sigma\left(\mathbf{w}^{\top} x\right) \sigma\left(\mathbf{w}^{\top} y\right)+\left(x^{\top} y\right) \sigma^{\prime}\left(\mathbf{w}^{\top} x\right) \sigma^{\prime}\left(\mathbf{w}^{\top} y\right)\right]
$$

- with RELU networks, we obtain a dot-product kernel.

## Kernels for deep models: dot-product kernels + Nyström

The Nyström method consists of replacing any point $\varphi(\mathbf{x})$ in $\mathcal{H}$, for $\mathbf{x}$ in $\mathcal{X}$ by its orthogonal projection onto a finite-dimensional subspace

$$
\mathcal{F}=\operatorname{span}\left(\varphi\left(\mathbf{z}_{1}\right), \ldots, \varphi\left(\mathbf{z}_{p}\right)\right)
$$

for some anchor points $\mathbf{Z}=\left[\mathbf{z}_{1}, \ldots, \mathbf{z}_{p}\right]$ in $\mathbb{R}^{d \times p}$

## Kernels for deep models: dot-product kernels + Nyström

The projection is equivalent to

$$
\Pi_{\mathcal{F}}[\mathbf{x}]:=\sum_{j=1}^{p} \beta_{j}^{\star} \varphi\left(\mathbf{z}_{j}\right) \quad \text { with } \quad \boldsymbol{\beta}^{\star} \in \underset{\boldsymbol{\beta} \in \mathbb{R}^{p}}{\operatorname{argmin}}\left\|\varphi(\mathbf{x})-\sum_{j=1}^{p} \beta_{j} \varphi\left(\mathbf{z}_{j}\right)\right\|_{\mathcal{H}}^{2},
$$

Then, it is possible to show that with $K(\mathbf{x}, \mathbf{y})=\kappa(\langle\mathbf{x}, \mathbf{y}\rangle)$,

$$
K(\mathbf{x}, \mathbf{y}) \approx\left\langle\Pi_{\mathcal{F}}[\mathbf{x}], \Pi_{\mathcal{F}}[\mathbf{y}]\right\rangle_{\mathcal{H}}=\langle\psi(\mathbf{x}), \psi(\mathbf{y})\rangle_{\mathbb{R}^{p}}
$$

with

$$
\psi(\mathbf{x})=\kappa\left(\mathbf{Z}^{\top} \mathbf{Z}\right)^{-1 / 2} \kappa\left(\mathbf{Z}^{\top} \mathbf{x}\right)
$$

where the function $\kappa$ is applied pointwise to its arguments. The resulting $\psi$ can be interpreted as a neural network performing (i) linear operation, (ii) pointwise non-linearity, (iii) linear operation.

## Kernels for deep models: end-to-end learning

Nyström's encoding with a dot-product kernel provides the encoding

$$
\psi_{\mathbf{Z}}(\mathbf{x})=\kappa\left(\mathbf{Z}^{\top} \mathbf{Z}\right)^{-1 / 2} \kappa\left(\mathbf{Z}^{\top} \mathbf{x}\right)
$$

The anchor points $\mathbf{Z}$ can be learned in various manners

- unsupervised learning: use K-means!
- supervised learning: use back-propagation

$$
\min _{\mathbf{w}, \mathbf{Z}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, \mathbf{w}^{\top} \psi_{\mathbf{Z}}\left(\mathbf{x}_{i}\right)\right)+\lambda\|\mathbf{w}\|^{2}
$$

## Kernels for deep models: end-to-end learning

Nyström's encoding with a dot-product kernel provides the encoding

$$
\psi_{\mathbf{Z}}(\mathbf{x})=\kappa\left(\mathbf{Z}^{\top} \mathbf{Z}\right)^{-1 / 2} \kappa\left(\mathbf{Z}^{\top} \mathbf{x}\right)
$$

The anchor points $\mathbf{Z}$ can be learned in various manners

- unsupervised learning: use K-means!
- supervised learning: use back-propagation

$$
\min _{\mathbf{w}, \mathbf{Z}} \frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, \mathbf{w}^{\top} \psi_{\mathbf{Z}}\left(\mathbf{x}_{i}\right)\right)+\lambda\|\mathbf{w}\|^{2}
$$

end-to-end learning with kernels may mean learning a parametrized linear subspace of the RKHS, where we project the data.

## Kernels for deep models: Convolutional Kernel Networks

What is the relation?

- it is possible to design functional spaces $\mathcal{H}$ where deep neural networks live (Mairal, 2016).

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)=\langle f, \Phi(x)\rangle_{\mathcal{H}}
$$

- we call the construction "convolutional kernel networks".

## Kernels for deep models: Convolutional Kernel Networks

What is the relation?

- it is possible to design functional spaces $\mathcal{H}$ where deep neural networks live (Mairal, 2016).

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)=\langle f, \Phi(x)\rangle_{\mathcal{H}}
$$

- we call the construction "convolutional kernel networks".

## Simple story about CKNs (Mairal, 2016)

- for the theory part, replace $\mathbf{x} \mapsto \sigma(\mathbf{A x})$ at each CNN layer by a kernel mapping $\mathbf{x} \mapsto \varphi(\mathbf{x})$ associated to a dot-product kernel.
- for the practical part, replace $\mathbf{x} \mapsto \sigma(\mathbf{A} \mathbf{x})$ by Nyström's embedding $\mathbf{x} \mapsto \kappa\left(\mathbf{Z}^{\top} \mathbf{Z}\right)^{-1 / 2} \kappa\left(\mathbf{Z}^{\top} \mathbf{x}\right)$. Then, you can either use K-means to learn the anchor points (unsupervised learning), or use back-propagation (supervised learning).

## Kernels for deep models: Convolutional Kernel Networks

What is the relation?

- it is possible to design functional spaces $\mathcal{H}$ where deep neural networks live (Mairal, 2016).

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)=\langle f, \Phi(x)\rangle_{\mathcal{H}}
$$

- we call the construction "convolutional kernel networks".

Why do we care?

- $\Phi(x)$ is related to the network architecture and is independent of training data. Is it stable? Does it lose signal information?
- $f$ is a predictive model. Can we control its stability?

$$
\left|f(x)-f\left(x^{\prime}\right)\right| \leq\|f\|_{\mathcal{H}}\left\|\Phi(x)-\Phi\left(x^{\prime}\right)\right\|_{\mathcal{H}} .
$$

## Construction of the RKHS for continuous signals

Initial map $x_{0}$ in $L^{2}\left(\Omega, \mathcal{H}_{0}\right)$
$x_{0}: \Omega \rightarrow \mathcal{H}_{0}$ : continuous signal, with $\Omega=\mathbb{R}^{d}$ ( $d=2$ for images).

- $x_{0}(u) \in \mathcal{H}_{0}$ : input value at location $u \quad\left(\mathcal{H}_{0}=\mathbb{R}^{3}\right.$ for RGB images).

## Construction of the RKHS for continuous signals

Initial map $x_{0}$ in $L^{2}\left(\Omega, \mathcal{H}_{0}\right)$
$x_{0}: \Omega \rightarrow \mathcal{H}_{0}$ : continuous signal, with $\Omega=\mathbb{R}^{d}$ ( $d=2$ for images).

- $x_{0}(u) \in \mathcal{H}_{0}$ : input value at location $u \quad\left(\mathcal{H}_{0}=\mathbb{R}^{3}\right.$ for RGB images).

Building map $x_{k}$ in $L^{2}\left(\Omega, \mathcal{H}_{k}\right)$ from $x_{k-1}$ in $L^{2}\left(\Omega, \mathcal{H}_{k-1}\right)$
$x_{k}: \Omega \rightarrow \mathcal{H}_{k}$ : feature map at layer $k$

$$
P_{k} x_{k-1}
$$

- $P_{k}$ : patch extraction operator, extract small patch of feature map $x_{k-1}$ around each point $u\left(P_{k} x_{k-1}(u)\right.$ is a patch centered at $\left.u\right)$.

## Construction of the RKHS for continuous signals

Initial map $x_{0}$ in $L^{2}\left(\Omega, \mathcal{H}_{0}\right)$
$x_{0}: \Omega \rightarrow \mathcal{H}_{0}$ : continuous signal, with $\Omega=\mathbb{R}^{d}$ ( $d=2$ for images).

- $x_{0}(u) \in \mathcal{H}_{0}$ : input value at location $u \quad\left(\mathcal{H}_{0}=\mathbb{R}^{3}\right.$ for RGB images).

Building map $x_{k}$ in $L^{2}\left(\Omega, \mathcal{H}_{k}\right)$ from $x_{k-1}$ in $L^{2}\left(\Omega, \mathcal{H}_{k-1}\right)$
$x_{k}: \Omega \rightarrow \mathcal{H}_{k}$ : feature map at layer $k$

$$
M_{k} P_{k} x_{k-1} .
$$

- $P_{k}$ : patch extraction operator, extract small patch of feature map $x_{k-1}$ around each point $u\left(P_{k} x_{k-1}(u)\right.$ is a patch centered at $\left.u\right)$.
- $M_{k}$ : non-linear mapping operator, maps each patch to a new Hilbert space $\mathcal{H}_{k}$ with a pointwise non-linear function $\varphi_{k}(\cdot)$.

## Construction of the RKHS for continuous signals

Initial map $x_{0}$ in $L^{2}\left(\Omega, \mathcal{H}_{0}\right)$
$x_{0}: \Omega \rightarrow \mathcal{H}_{0}$ : continuous signal, with $\Omega=\mathbb{R}^{d}$ ( $d=2$ for images).

- $x_{0}(u) \in \mathcal{H}_{0}$ : input value at location $u \quad\left(\mathcal{H}_{0}=\mathbb{R}^{3}\right.$ for RGB images).

Building map $x_{k}$ in $L^{2}\left(\Omega, \mathcal{H}_{k}\right)$ from $x_{k-1}$ in $L^{2}\left(\Omega, \mathcal{H}_{k-1}\right)$
$x_{k}: \Omega \rightarrow \mathcal{H}_{k}$ : feature map at layer $k$

$$
x_{k}=A_{k} M_{k} P_{k} x_{k-1}
$$

- $P_{k}$ : patch extraction operator, extract small patch of feature map $x_{k-1}$ around each point $u\left(P_{k} x_{k-1}(u)\right.$ is a patch centered at $\left.u\right)$.
- $M_{k}$ : non-linear mapping operator, maps each patch to a new Hilbert space $\mathcal{H}_{k}$ with a pointwise non-linear function $\varphi_{k}(\cdot)$.
- $A_{k}$ : (linear) pooling operator at scale $\sigma_{k}$.

## Construction of the RKHS for continuous signals

## Construction of the RKHS for continuous signals

Kernel mapping for patches

- We use a homogeneous dot-product kernel for image patches

$$
K\left(z, z^{\prime}\right)=\|z\|\left\|z^{\prime}\right\| \kappa\left(\frac{\left\langle z, z^{\prime}\right\rangle}{\|z\|\left\|z^{\prime}\right\|}\right) .
$$

Multilayer representation

$$
\Phi_{n}(x)=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} x_{0} \in L^{2}\left(\Omega, \mathcal{H}_{n}\right) .
$$

- $\sigma_{k}$ grows exponentially in practice (i.e., fixed with subsampling).

## Construction of the RKHS for continuous signals

Kernel mapping for patches

- We use a homogeneous dot-product kernel for image patches

$$
K\left(z, z^{\prime}\right)=\|z\|\left\|z^{\prime}\right\| \kappa\left(\frac{\left\langle z, z^{\prime}\right\rangle}{\|z\|\left\|z^{\prime}\right\|}\right) .
$$

Multilayer representation

$$
\Phi_{n}(x)=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} x_{0} \in L^{2}\left(\Omega, \mathcal{H}_{n}\right) .
$$

- $\sigma_{k}$ grows exponentially in practice (i.e., fixed with subsampling).

Prediction layer

- e.g., linear $f(x)=\left\langle w, \Phi_{n}(x)\right\rangle$.
- "linear kernel" $\mathcal{K}\left(x, x^{\prime}\right)=\left\langle\Phi_{n}(x), \Phi_{n}\left(x^{\prime}\right)\right\rangle=\int_{\Omega}\left\langle x_{n}(u), x_{n}^{\prime}(u)\right\rangle d u$.

## Convolutional Kernel Networks in practice

Learning mechanism of CKNs between layers 0 and 1 .

## Convolutional Kernel Networks in Practice

What is the difference with a CNN?

- Given a patch $x$, a CNN computes $\psi_{C N N}(\mathbf{x})=\sigma\left(\mathbf{Z}^{\top} \mathbf{x}\right)$.
- whereas a CKN computes $\psi_{C K N}(\mathbf{x})=\|\mathbf{x}\| \kappa\left(\mathbf{Z}^{\top} \mathbf{Z}\right)^{-1 / 2} \kappa\left(\mathbf{Z}^{\top} \mathbf{x} /\|\mathbf{x}\|\right)$.

## Convolutional Kernel Networks in Practice

## What is the difference with a CNN?

- Given a patch $x$, a CNN computes $\psi_{C N N}(\mathbf{x})=\sigma\left(\mathbf{Z}^{\top} \mathbf{x}\right)$.
- whereas a CKN computes $\psi_{C K N}(\mathbf{x})=\|\mathbf{x}\| \kappa\left(\mathbf{Z}^{\top} \mathbf{Z}\right)^{-1 / 2} \kappa\left(\mathbf{Z}^{\top} \mathbf{x} /\|\mathbf{x}\|\right)$.

## Consequences

- we have a geometric interpretation in terms of subspace learning.
- it provides unsupervised learning mechanisms (Nyström).
- supervised learning is feasible.
- the kernel interpretation provides regularization mechanisms.
- kernel representations can possibly be used in other contexts (statistical testing? kernel PCA? CCA? K-means?).

## Experiments

- Briefly state-of-the-art for image retrieval (Paulin et al., 2015);
- Briefly state-of-the-art for image super-resolution (Mairal, 2016);

## Interesting findings from CIFAR-10

- about $92 \%$ with supervision, mild data augmentation, 14 layers, 256 anchor points per layers (no need for batch norm, vanilla SGD+momentum).
- about $86 \%$ with no supervision for a two-layer model with a huge number of anchor points (1024-16384) and no data augmentation.
- with no supervision, the performance monotonically increases with the dimension (better kernel approximation).
- computing the exact kernel does not make sense in practice for computational reasons, but it is feasible with lots of CPUs; it yields about $90 \%$ with three layers (unpublished, by A. Bietti), which is consistent with (Shankar et al., 2020).

## Other relations between kernels and deep learning

- hierarchical kernel descriptors (Bo et al., 2011);
- other multilayer models (Bouvrie et al., 2009; Montavon et al., 2011; Anselmi et al., 2015);
- deep Gaussian processes (Damianou and Lawrence, 2013).
- multilayer PCA (Schölkopf et al., 1998).
- old kernels for images (Scholkopf, 1997), related to one-layer CKN.
- RBF networks (Broomhead and Lowe, 1988).

## Outline

(6) Open Problems and Research Topics

- Multiple Kernel Learning (MKL)
- Large-scale learning with kernels
- Foundations of deep learning from a kernel point of view
- Motivation
- Deep kernel machines
- Deep learning and stability
- Application to graphs
- Application to biological sequences

## Focus on convolutional kernel networks (CKNs)

What is the relation?

- it is possible to design functional spaces $\mathcal{H}$ for deep neural networks (Mairal, 2016).

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)=\langle f, \Phi(x)\rangle_{\mathcal{H}}
$$

- we call the construction "convolutional kernel networks" (in short, replace $u \mapsto \sigma(\langle a, u\rangle)$ by a kernel mapping $u \mapsto \varphi_{k}(u)$.

Why do we care?

- $\Phi(x)$ is related to the network architecture and is independent of training data. Is it stable? Does it lose signal information?

## Focus on convolutional kernel networks (CKNs)

What is the relation?

- it is possible to design functional spaces $\mathcal{H}$ for deep neural networks (Mairal, 2016).

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)=\langle f, \Phi(x)\rangle_{\mathcal{H}}
$$

- we call the construction "convolutional kernel networks" (in short, replace $u \mapsto \sigma(\langle a, u\rangle)$ by a kernel mapping $u \mapsto \varphi_{k}(u)$.

Why do we care?

- $\Phi(x)$ is related to the network architecture and is independent of training data. Is it stable? Does it lose signal information?
- $f$ is a predictive model. Can we control its stability?

$$
\left|f(x)-f\left(x^{\prime}\right)\right| \leq\|f\|_{\mathcal{H}}\left\|\Phi(x)-\Phi\left(x^{\prime}\right)\right\|_{\mathcal{H}} .
$$

## Summary of the results from Bietti and Mairal (2019a)

Multi-layer construction of the RKHS H

- Contains CNNs with smooth homogeneous activations functions.

## Summary of the results from Bietti and Mairal (2019a)

Multi-layer construction of the RKHS H

- Contains CNNs with smooth homogeneous activations functions.

Signal representation: Conditions for

- Signal preservation of the multi-layer kernel mapping $\Phi$.
- Stability to deformations and non-expansiveness for $\Phi$.
- Constructions to achieve group invariance.

## Summary of the results from Bietti and Mairal (2019a)

Multi-layer construction of the RKHS H

- Contains CNNs with smooth homogeneous activations functions.

Signal representation: Conditions for

- Signal preservation of the multi-layer kernel mapping $\Phi$.
- Stability to deformations and non-expansiveness for $\Phi$.
- Constructions to achieve group invariance.

On learning

- Bounds on the RKHS norm $\|.\|_{\mathcal{H}}$ to control stability and generalization of a predictive model $f$.

$$
\left|f(x)-f\left(x^{\prime}\right)\right| \leq\|f\|_{\mathcal{H}}\left\|\Phi(x)-\Phi\left(x^{\prime}\right)\right\|_{\mathcal{H}}
$$

## Smooth homogeneous activations functions

$$
z \mapsto \operatorname{ReLU}\left(w^{\top} z\right) \quad \Longrightarrow \quad z \mapsto\|z\| \sigma\left(w^{\top} z /\|z\|\right)
$$

## Stability to deformations

## Deformations

- $\tau: \Omega \rightarrow \Omega: C^{1}$-diffeomorphism
- $L_{\tau} x(u)=x(u-\tau(u))$ : action operator
- Much richer group of transformations than translations

$$
\begin{array}{llllllllll}
4 & 4 & 4 & 4 & 4 & 4 & 4 & 4 & 4 & 4 \\
5 & 5 & 5 & 5 & 5 & 5 & 5 & 5 & 5 & 5 \\
7 & 7 & 7 & 7 & 7 & 1 & 7 & 7 & 7 & 7 \\
8 & 8 & 8 & 8 & 8 & 8 & 8 & 8 & 8 & 8
\end{array}
$$

- Studied for wavelet-based scattering transform (Mallat, 2012; Bruna and Mallat, 2013)

## Stability to deformations

## Deformations

- $\tau: \Omega \rightarrow \Omega: C^{1}$-diffeomorphism
- $L_{\tau} x(u)=x(u-\tau(u))$ : action operator
- Much richer group of transformations than translations

Definition of stability

- Representation $\Phi(\cdot)$ is stable (Mallat, 2012) if:

$$
\left\|\Phi\left(L_{\tau} x\right)-\Phi(x)\right\| \leq\left(C_{1}\|\nabla \tau\|_{\infty}+C_{2}\|\tau\|_{\infty}\right)\|x\|
$$

- $\|\nabla \tau\|_{\infty}=\sup _{u}\|\nabla \tau(u)\|$ controls deformation
- $\|\tau\|_{\infty}=\sup _{u}|\tau(u)|$ controls translation
- $C_{2} \rightarrow 0$ : translation invariance

## Smoothness and stability with kernels

Geometry of the kernel mapping: $f(x)=\langle f, \Phi(x)\rangle$

$$
\left|f(x)-f\left(x^{\prime}\right)\right| \leq\|f\|_{\mathcal{H}} \cdot\left\|\Phi(x)-\Phi\left(x^{\prime}\right)\right\|_{\mathcal{H}}
$$

- $\|f\|_{\mathcal{H}}$ controls complexity of the model
- $\Phi(x)$ encodes CNN architecture independently of the model (smoothness, invariance, stability to deformations)

## Smoothness and stability with kernels

Geometry of the kernel mapping: $f(x)=\langle f, \Phi(x)\rangle$

$$
\left|f(x)-f\left(x^{\prime}\right)\right| \leq\|f\|_{\mathcal{H}} \cdot\left\|\Phi(x)-\Phi\left(x^{\prime}\right)\right\|_{\mathcal{H}}
$$

- $\|f\|_{\mathcal{H}}$ controls complexity of the model
- $\Phi(x)$ encodes CNN architecture independently of the model (smoothness, invariance, stability to deformations)

Useful kernels in practice:

- Convolutional kernel networks (CKNs, Mairal, 2016) with efficient approximations
- Extends to neural tangent kernels (NTKs, Jacot et al., 2018) of infinitely wide CNNs (Bietti and Mairal, 2019b)

## Recap: Construction of the RKHS for continuous signals

## Patch extraction operator $P_{k}$

$$
P_{k} x_{k-1}(u):=\left(x_{k-1}(u+v)\right)_{v \in S_{k}} \in \mathcal{P}_{k}=\mathcal{H}_{k-1}^{S_{k}}
$$

## Patch extraction operator $P_{k}$

$$
P_{k} x_{k-1}(u):=\left(x_{k-1}(u+v)\right)_{v \in S_{k}} \in \mathcal{P}_{k}=\mathcal{H}_{k-1}^{S_{k}}
$$

- $S_{k}$ : patch shape, e.g. box

## Non-linear mapping operator $M_{k}$

$$
M_{k} P_{k} x_{k-1}(u):=\varphi_{k}\left(P_{k} x_{k-1}(u)\right) \in \mathcal{H}_{k}
$$

## Non-linear mapping operator $M_{k}$

$$
M_{k} P_{k} x_{k-1}(u):=\varphi_{k}\left(P_{k} x_{k-1}(u)\right) \in \mathcal{H}_{k}
$$

Kernel mapping of homogeneous dot-product kernels:

$$
K_{k}\left(z, z^{\prime}\right)=\|z\|\left\|z^{\prime}\right\| \kappa_{k}\left(\frac{\left\langle z, z^{\prime}\right\rangle}{\|z\|\left\|z^{\prime}\right\|}\right)=\left\langle\varphi_{k}(z), \varphi_{k}\left(z^{\prime}\right)\right\rangle
$$

$\kappa_{k}(u)=\sum_{j=0}^{\infty} b_{j} u^{j}$ with $b_{j} \geq 0, \kappa_{k}(1)=1$

## Examples

- $\kappa_{\exp }\left(\left\langle z, z^{\prime}\right\rangle\right)=e^{\left\langle z, z^{\prime}\right\rangle-1}$ (Gaussian kernel on the sphere)
- $\kappa_{\text {inv-poly }}\left(\left\langle z, z^{\prime}\right\rangle\right)=\frac{1}{2-\left\langle z, z^{\prime}\right\rangle}$

## Pooling operator $A_{k}$

$$
x_{k}(u)=A_{k} M_{k} P_{k} x_{k-1}(u)=\int_{\mathbb{R}^{d}} h_{\sigma_{k}}(u-v) M_{k} P_{k} x_{k-1}(v) d v \in \mathcal{H}_{k}
$$

## Pooling operator $A_{k}$

$$
x_{k}(u)=A_{k} M_{k} P_{k} x_{k-1}(u)=\int_{\mathbb{R}^{d}} h_{\sigma_{k}}(u-v) M_{k} P_{k} x_{k-1}(v) d v \in \mathcal{H}_{k}
$$

- $h_{\sigma_{k}}$ : pooling filter at scale $\sigma_{k}$
- $h_{\sigma_{k}}(u):=\sigma_{k}^{-d} h\left(u / \sigma_{k}\right)$ with $h(u)$ Gaussian
- linear, non-expansive operator: $\left\|A_{k}\right\| \leq 1$

## Pooling operator $A_{k}$

$$
x_{k}(u)=A_{k} M_{k} P_{k} x_{k-1}(u)=\int_{\mathbb{R}^{d}} h_{\sigma_{k}}(u-v) M_{k} P_{k} x_{k-1}(v) d v \in \mathcal{H}_{k}
$$

- $h_{\sigma_{k}}$ : pooling filter at scale $\sigma_{k}$
- $h_{\sigma_{k}}(u):=\sigma_{k}^{-d} h\left(u / \sigma_{k}\right)$ with $h(u)$ Gaussian
- linear, non-expansive operator: $\left\|A_{k}\right\| \leq 1$
- In practice: discretization, sampling at resolution $\sigma_{k}$ after pooling
- "Preserves information" when subsampling $\leq$ patch size

Recap: $P_{k}, M_{k}, A_{k}$

## Recap: multilayer construction

## Multilayer representation

$$
\Phi\left(x_{0}\right)=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} x_{0} \in L^{2}\left(\Omega, \mathcal{H}_{n}\right) .
$$

- $S_{k}, \sigma_{k}$ grow exponentially in practice (i.e., fixed with subsampling).

## Recap: multilayer construction

## Multilayer representation

$$
\Phi\left(x_{0}\right)=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} x_{0} \in L^{2}\left(\Omega, \mathcal{H}_{n}\right) .
$$

- $S_{k}, \sigma_{k}$ grow exponentially in practice (i.e., fixed with subsampling).

## Assumption on $x_{0}$

- $x_{0}$ is typically a discrete signal aquired with physical device.
- Natural assumption: $x_{0}=A_{0} x$, with $x$ the original continuous signal, $A_{0}$ local integrator with scale $\sigma_{0}$ (anti-aliasing).

## Recap: multilayer construction

## Multilayer representation

$$
\Phi\left(x_{0}\right)=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} x_{0} \in L^{2}\left(\Omega, \mathcal{H}_{n}\right) .
$$

- $S_{k}, \sigma_{k}$ grow exponentially in practice (i.e., fixed with subsampling).

## Assumption on $x_{0}$

- $x_{0}$ is typically a discrete signal aquired with physical device.
- Natural assumption: $x_{0}=A_{0} x$, with $x$ the original continuous signal, $A_{0}$ local integrator with scale $\sigma_{0}$ (anti-aliasing).

Final kernel

$$
K_{C K N}\left(x, x^{\prime}\right)=\left\langle\Phi(x), \Phi\left(x^{\prime}\right)\right\rangle_{L^{2}(\Omega)}=\int_{\Omega}\left\langle x_{n}(u), x_{n}^{\prime}(u)\right\rangle d u
$$

## Warmup: translation invariance

## Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve translation invariance?

- Translation: $L_{c} x(u)=x(u-c)$.

## Warmup: translation invariance

## Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve translation invariance?

- Translation: $L_{c} x(u)=x(u-c)$.
- Equivariance - all operators commute with $L_{c}$ : $\square L_{c}=L_{c} \square$.

$$
\begin{aligned}
\left\|\Phi_{n}\left(L_{c} x\right)-\Phi_{n}(x)\right\| & =\left\|L_{c} \Phi_{n}(x)-\Phi_{n}(x)\right\| \\
& \leq\left\|L_{c} A_{n}-A_{n}\right\| \cdot\left\|M_{n} P_{n} \Phi_{n-1}(x)\right\| \\
& \leq\left\|L_{c} A_{n}-A_{n}\right\|\|x\| .
\end{aligned}
$$

## Warmup: translation invariance

## Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve translation invariance?

- Translation: $L_{c} x(u)=x(u-c)$.
- Equivariance - all operators commute with $L_{c}$ : $\square L_{c}=L_{c} \square$.

$$
\begin{aligned}
\left\|\Phi_{n}\left(L_{c} x\right)-\Phi_{n}(x)\right\| & =\left\|L_{c} \Phi_{n}(x)-\Phi_{n}(x)\right\| \\
& \leq\left\|L_{c} A_{n}-A_{n}\right\| \cdot\left\|M_{n} P_{n} \Phi_{n-1}(x)\right\| \\
& \leq\left\|L_{c} A_{n}-A_{n}\right\|\|x\| .
\end{aligned}
$$

- Mallat (2012): $\left\|L_{\tau} A_{n}-A_{n}\right\| \leq \frac{C_{2}}{\sigma_{n}}\|\tau\|_{\infty}$
(operator norm).

## Warmup: translation invariance

## Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve translation invariance?

- Translation: $L_{c} x(u)=x(u-c)$.
- Equivariance - all operators commute with $L_{c}$ : $\square L_{c}=L_{c} \square$.

$$
\begin{aligned}
\left\|\Phi_{n}\left(L_{c} x\right)-\Phi_{n}(x)\right\| & =\left\|L_{c} \Phi_{n}(x)-\Phi_{n}(x)\right\| \\
& \leq\left\|L_{c} A_{n}-A_{n}\right\| \cdot\left\|M_{n} P_{n} \Phi_{n-1}(x)\right\| \\
& \leq\left\|L_{c} A_{n}-A_{n}\right\|\|x\| .
\end{aligned}
$$

- Mallat (2012): $\left\|L_{c} A_{n}-A_{n}\right\| \leq \frac{C_{2}}{\sigma_{n}} c$ (operator norm).
- Scale $\sigma_{n}$ of the last layer controls translation invariance.

## Stability to deformations

Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve stability to deformations?

- Patch extraction $P_{k}$ and pooling $A_{k}$ do not commute with $L_{\tau}$ !

## Stability to deformations

Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve stability to deformations?

- Patch extraction $P_{k}$ and pooling $A_{k}$ do not commute with $L_{\tau}$ !
- $\left\|A_{k} L_{\tau}-L_{\tau} A_{k}\right\| \leq C_{1}\|\nabla \tau\|_{\infty}$ (from Mallat, 2012).

## Stability to deformations

Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve stability to deformations?

- Patch extraction $P_{k}$ and pooling $A_{k}$ do not commute with $L_{\tau}$ !
- $\left\|\left[A_{k}, L_{\tau}\right]\right\| \leq C_{1}\|\nabla \tau\|_{\infty}$ (from Mallat, 2012).

## Stability to deformations

Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve stability to deformations?

- Patch extraction $P_{k}$ and pooling $A_{k}$ do not commute with $L_{\tau}$ !
- $\left\|\left[A_{k}, L_{\tau}\right]\right\| \leq C_{1}\|\nabla \tau\|_{\infty}$ (from Mallat, 2012).
- But: $\left[P_{k}, L_{\tau}\right]$ is unstable at high frequencies!

## Stability to deformations

Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve stability to deformations?

- Patch extraction $P_{k}$ and pooling $A_{k}$ do not commute with $L_{\tau}$ !
- $\left\|\left[A_{k}, L_{\tau}\right]\right\| \leq C_{1}\|\nabla \tau\|_{\infty}$ (from Mallat, 2012).
- But: $\left[P_{k}, L_{\tau}\right]$ is unstable at high frequencies!
- Adapt to current layer resolution, patch size controlled by $\sigma_{k-1}$ :

$$
\left\|\left[P_{k} A_{k-1}, L_{\tau}\right]\right\| \leq C_{1, \kappa}\|\nabla \tau\|_{\infty} \quad \sup _{u \in S_{k}}|u| \leq \kappa \sigma_{k-1}
$$

## Stability to deformations

Representation

$$
\Phi_{n}(x):=A_{n} M_{n} P_{n} A_{n-1} M_{n-1} P_{n-1} \cdots A_{1} M_{1} P_{1} A_{0} x
$$

How to achieve stability to deformations?

- Patch extraction $P_{k}$ and pooling $A_{k}$ do not commute with $L_{\tau}$ !
- $\left\|\left[A_{k}, L_{\tau}\right]\right\| \leq C_{1}\|\nabla \tau\|_{\infty}$ (from Mallat, 2012).
- But: $\left[P_{k}, L_{\tau}\right]$ is unstable at high frequencies!
- Adapt to current layer resolution, patch size controlled by $\sigma_{k-1}$ :

$$
\left\|\left[P_{k} A_{k-1}, L_{\tau}\right]\right\| \leq C_{1, \kappa}\|\nabla \tau\|_{\infty} \quad \sup _{u \in S_{k}}|u| \leq \kappa \sigma_{k-1}
$$

- $C_{1, \kappa}$ grows as $\kappa^{d+1} \Longrightarrow$ more stable with small patches (e.g., $3 \times 3$, VGG et al.).

## Stability to deformations

## Theorem (Stability of CKN (Bietti and Mairal, 2019a))

 Let $\Phi_{n}(x)=\Phi\left(A_{0} x\right)$ and assume $\|\nabla \tau\|_{\infty} \leq 1 / 2$,$$
\left\|\Phi_{n}\left(L_{\tau} x\right)-\Phi_{n}(x)\right\| \leq\left(C_{\beta}(n+1)\|\nabla \tau\|_{\infty}+\frac{C}{\sigma_{n}}\|\tau\|_{\infty}\right)\|x\|
$$

- Translation invariance: large $\sigma_{n}$
- Stability: small patch sizes ( $\beta \approx$ patch size, $C_{\beta}=O\left(\beta^{3}\right)$ for images)
- Signal preservation: subsampling factor $\approx$ patch size
$\Longrightarrow$ need several layers with small
patches $n=O\left(\log \left(\sigma_{n} / \sigma_{0}\right) / \log \beta\right)$

## Stability to deformations

## Theorem (Stability of CKN (Bietti and Mairal, 2019a))

Let $\Phi_{n}(x)=\Phi\left(A_{0} x\right)$ and assume $\|\nabla \tau\|_{\infty} \leq 1 / 2$,

$$
\left\|\Phi_{n}\left(L_{\tau} x\right)-\Phi_{n}(x)\right\| \leq\left(C_{\beta}(n+1)\|\nabla \tau\|_{\infty}+\frac{C}{\sigma_{n}}\|\tau\|_{\infty}\right)\|x\|
$$

- Translation invariance: large $\sigma_{n}$
- Stability: small patch sizes ( $\beta \approx$ patch size, $C_{\beta}=O\left(\beta^{3}\right)$ for images)
- Signal preservation: subsampling factor $\approx$ patch size
$\Longrightarrow$ need several layers with small
patches $n=O\left(\log \left(\sigma_{n} / \sigma_{0}\right) / \log \beta\right)$
- Achieved by controlling norm of commutator $\left[L_{\tau}, P_{k} A_{k-1}\right.$ ]
- Extend result by Mallat (2012) for controlling $\left\|\left[L_{\tau}, A\right]\right\|$
- Need patches $S_{k}$ adapted to resolution $\sigma_{k-1}$ : $\operatorname{diam} S_{k} \leq \beta \sigma_{k-1}$

## Beyond the translation group

Can we achieve invariance to other groups?

- Group action: $\operatorname{Lg} x(u)=x\left(g^{-1} u\right)$ (e.g., rotations, reflections).
- Feature maps $x(u)$ defined on $u \in G$ ( $G$ : locally compact group).

## Beyond the translation group

Can we achieve invariance to other groups?

- Group action: $\operatorname{Lg}_{g} x(u)=x\left(g^{-1} u\right)$ (e.g., rotations, reflections).
- Feature maps $x(u)$ defined on $u \in G$ ( $G$ : locally compact group).

Recipe: Equivariant inner layers + global pooling in last layer

- Patch extraction:

$$
P x(u)=(x(u v))_{v \in S} .
$$

- Non-linear mapping: equivariant because pointwise!
- Pooling ( $\mu$ : left-invariant Haar measure):

$$
A x(u)=\int_{G} x(u v) h(v) d \mu(v)=\int_{G} x(v) h\left(u^{-1} v\right) d \mu(v)
$$

related work (Sifre and Mallat, 2013; Cohen and Welling, 2016; Raj et al., 2016)...

## Stability to deformations for convolutional NTK

Theorem (Stability of NTK (Bietti and Mairal, 2019b))
Let $\Phi_{n}(x)=\Phi^{N T K}\left(A_{0} x\right)$, and assume $\|\nabla \tau\|_{\infty} \leq 1 / 2$

$$
\begin{aligned}
& \left\|\Phi_{n}\left(L_{\tau} x\right)-\Phi_{n}(x)\right\| \\
& \quad \leq\left(C_{\beta} n^{7 / 4}\|\nabla \tau\|_{\infty}^{1 / 2}+C_{\beta}^{\prime} n^{2}\|\nabla \tau\|_{\infty}+\sqrt{n+1} \frac{C}{\sigma_{n}}\|\tau\|_{\infty}\right)\|x\|,
\end{aligned}
$$

## Discretization and signal preservation: example in 1D

- Discrete signal $\overline{x_{k}}$ in $\ell^{2}\left(\mathbb{Z}, \overline{\mathcal{H}}_{k}\right)$ vs continuous ones $x_{k}$ in $L^{2}\left(\mathbb{R}, \mathcal{H}_{k}\right)$.
- $\bar{x}_{k}$ : subsampling factor $s_{k}$ after pooling with scale $\sigma_{k} \approx s_{k}$ :

$$
\bar{x}_{k}[n]=\bar{A}_{k} \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}\left[n s_{k}\right] .
$$

## Discretization and signal preservation: example in 1D

- Discrete signal $\overline{x_{k}}$ in $\ell^{2}\left(\mathbb{Z}, \overline{\mathcal{H}}_{k}\right)$ vs continuous ones $x_{k}$ in $L^{2}\left(\mathbb{R}, \mathcal{H}_{k}\right)$.
- $\bar{x}_{k}$ : subsampling factor $s_{k}$ after pooling with scale $\sigma_{k} \approx s_{k}$ :

$$
\bar{x}_{k}[n]=\bar{A}_{k} \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}\left[n s_{k}\right] .
$$

- Claim: We can recover $\bar{x}_{k-1}$ from $\bar{x}_{k}$ if factor $s_{k} \leq$ patch size.

## Discretization and signal preservation: example in 1D

- Discrete signal $\overline{x_{k}}$ in $\ell^{2}\left(\mathbb{Z}, \overline{\mathcal{H}}_{k}\right)$ vs continuous ones $x_{k}$ in $L^{2}\left(\mathbb{R}, \mathcal{H}_{k}\right)$.
- $\bar{x}_{k}$ : subsampling factor $s_{k}$ after pooling with scale $\sigma_{k} \approx s_{k}$ :

$$
\bar{x}_{k}[n]=\bar{A}_{k} \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}\left[n s_{k}\right] .
$$

- Claim: We can recover $\bar{x}_{k-1}$ from $\bar{x}_{k}$ if factor $s_{k} \leq$ patch size.
- How? Recover patches with linear functions (contained in $\overline{\mathcal{H}}_{k}$ )

$$
\left\langle f_{w}, \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}(u)\right\rangle=f_{w}\left(\bar{P}_{k} \bar{x}_{k-1}(u)\right)=\left\langle w, \bar{P}_{k} \bar{x}_{k-1}(u)\right\rangle,
$$

and

$$
\bar{P}_{k} \bar{x}_{k-1}(u)=\sum_{w \in B}\left\langle f_{w}, \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}(u)\right\rangle w
$$

## Discretization and signal preservation: example in 1D

- Discrete signal $\bar{x}_{k}$ in $\ell^{2}\left(\mathbb{Z}, \overline{\mathcal{H}}_{k}\right)$ vs continuous ones $x_{k}$ in $L^{2}\left(\mathbb{R}, \mathcal{H}_{k}\right)$.
- $\bar{x}_{k}$ : subsampling factor $s_{k}$ after pooling with scale $\sigma_{k} \approx s_{k}$ :

$$
\bar{x}_{k}[n]=\bar{A}_{k} \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}\left[n n_{k}\right] .
$$

- Claim: We can recover $\bar{x}_{k-1}$ from $\bar{x}_{k}$ if factor $s_{k} \leq$ patch size.
- How? Recover patches with linear functions (contained in $\overline{\mathcal{H}}_{k}$ )

$$
\left\langle f_{w}, \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}(u)\right\rangle=f_{w}\left(\bar{P}_{k} \bar{x}_{k-1}(u)\right)=\left\langle w, \bar{P}_{k} \bar{x}_{k-1}(u)\right\rangle,
$$

and

$$
\bar{P}_{k} \bar{x}_{k-1}(u)=\sum_{w \in B}\left\langle f_{w}, \bar{M}_{k} \bar{P}_{k} \bar{x}_{k-1}(u)\right\rangle w .
$$

Warning: no claim that recovery is practical and/or stable.

## Discretization and signal preservation: example in 1D

## RKHS of patch kernels $K_{k}$

$$
K_{k}\left(z, z^{\prime}\right)=\|z\|\left\|z^{\prime}\right\| \kappa\left(\frac{\left\langle z, z^{\prime}\right\rangle}{\|z\|\left\|z^{\prime}\right\|}\right), \quad \kappa(u)=\sum_{j=0}^{\infty} b_{j} u^{j}
$$

What does the RKHS contain?

Homogeneous version of (Zhang et al., 2016, 2017)

## RKHS of patch kernels $K_{k}$

$$
K_{k}\left(z, z^{\prime}\right)=\|z\|\left\|z^{\prime}\right\| \kappa\left(\frac{\left\langle z, z^{\prime}\right\rangle}{\|z\|\left\|z^{\prime}\right\|}\right), \quad \kappa(u)=\sum_{j=0}^{\infty} b_{j} u^{j}
$$

What does the RKHS contain?

- RKHS contains homogeneous functions:

$$
f: z \mapsto\|z\| \sigma(\langle g, z\rangle /\|z\|) .
$$

Homogeneous version of (Zhang et al., 2016, 2017)

## RKHS of patch kernels $K_{k}$

$$
K_{k}\left(z, z^{\prime}\right)=\|z\|\left\|z^{\prime}\right\| \kappa\left(\frac{\left\langle z, z^{\prime}\right\rangle}{\|z\|\left\|z^{\prime}\right\|}\right), \quad \kappa(u)=\sum_{j=0}^{\infty} b_{j} u^{j}
$$

What does the RKHS contain?

- RKHS contains homogeneous functions:

$$
f: z \mapsto\|z\| \sigma(\langle g, z\rangle /\|z\|)
$$

- Smooth activations: $\sigma(u)=\sum_{j=0}^{\infty} a_{j} u^{j}$ with $a_{j} \geq 0$.
- Norm: $\|f\|_{\mathcal{H}_{k}}^{2} \leq C_{\sigma}^{2}\left(\|g\|^{2}\right)=\sum_{j=0}^{\infty} \frac{a_{j}^{2}}{b_{j}}\|g\|^{2}<\infty$.

Homogeneous version of (Zhang et al., 2016, 2017)

## RKHS of patch kernels $K_{k}$

## Examples:

- $\sigma(u)=u$ (linear): $C_{\sigma}^{2}\left(\lambda^{2}\right)=O\left(\lambda^{2}\right)$.
- $\sigma(u)=u^{p}$ (polynomial): $C_{\sigma}^{2}\left(\lambda^{2}\right)=O\left(\lambda^{2 p}\right)$.
- $\sigma \approx \sin$, sigmoid, smooth ReLU: $C_{\sigma}^{2}\left(\lambda^{2}\right)=O\left(e^{c \lambda^{2}}\right)$.

## Constructing a CNN in the RKHS $\mathcal{H}_{\mathcal{K}}$

Some CNNs live in the RKHS: "linearization" principle

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)=\langle f, \Phi(x)\rangle_{\mathcal{H}} .
$$

## Constructing a CNN in the RKHS $\mathcal{H}_{\mathcal{K}}$

Some CNNs live in the RKHS: "linearization" principle

$$
f(\mathbf{x})=\sigma_{k}\left(\mathbf{A}_{k} \sigma_{k-1}\left(\mathbf{A}_{k-1} \ldots \sigma_{2}\left(\mathbf{A}_{2} \sigma_{1}\left(\mathbf{A}_{1} \mathbf{x}\right)\right) \ldots\right)\right)=\langle f, \Phi(x)\rangle_{\mathcal{H}} .
$$

- Consider a CNN with filters $W_{k}^{i j}(u), u \in S_{k}$.
- k: layer;
- $i$ : index of filter;
- $j$ : index of input channel.
- "Smooth homogeneous" activations $\sigma$.
- The CNN can be constructed hierarchically in $\mathcal{H}_{\mathcal{K}}$.
- Norm (linear layers):

$$
\left\|f_{\sigma}\right\|^{2} \leq\left\|W_{n+1}\right\|_{2}^{2} \cdot\left\|W_{n}\right\|_{2}^{2} \cdot\left\|W_{n-1}\right\|_{2}^{2} \ldots\left\|W_{1}\right\|_{2}^{2}
$$

- Linear layers: product of spectral norms.

## Link with generalization

Direct application of classical generalization bounds

- Simple bound on Rademacher complexity for linear/kernel methods:

$$
\mathcal{F}_{B}=\left\{f \in \mathcal{H}_{\mathcal{K}},\|f\| \leq B\right\} \Longrightarrow \operatorname{Rad}_{N}\left(\mathcal{F}_{B}\right) \leq O\left(\frac{B R}{\sqrt{N}}\right)
$$

## Link with generalization

## Direct application of classical generalization bounds

- Simple bound on Rademacher complexity for linear/kernel methods:

$$
\mathcal{F}_{B}=\left\{f \in \mathcal{H}_{\mathcal{K}},\|f\| \leq B\right\} \Longrightarrow \operatorname{Rad}_{N}\left(\mathcal{F}_{B}\right) \leq O\left(\frac{B R}{\sqrt{N}}\right)
$$

- Leads to margin bound $O\left(\left\|\hat{f}_{N}\right\| R / \gamma \sqrt{N}\right)$ for a learned CNN $\hat{f}_{N}$ with margin (confidence) $\gamma>0$.
- Related to recent generalization bounds for neural networks based on product of spectral norms (e.g., Bartlett et al., 2017; Neyshabur et al., 2018).
(see, e.g., Boucheron et al., 2005; Shalev-Shwartz and Ben-David, 2014)...

## Deep convolutional representations: conclusions

Study of generic properties of signal representation

- Deformation stability with small patches, adapted to resolution.
- Signal preservation when subsampling $\leq$ patch size.
- Group invariance by changing patch extraction and pooling.

## Deep convolutional representations: conclusions

Study of generic properties of signal representation

- Deformation stability with small patches, adapted to resolution.
- Signal preservation when subsampling $\leq$ patch size.
- Group invariance by changing patch extraction and pooling.

Applies to learned models

- Same quantity $\|f\|$ controls stability and generalization.
- "higher capacity" is needed to discriminate small deformations.

## Deep convolutional representations: conclusions

Study of generic properties of signal representation

- Deformation stability with small patches, adapted to resolution.
- Signal preservation when subsampling $\leq$ patch size.
- Group invariance by changing patch extraction and pooling.

Applies to learned models

- Same quantity $\|f\|$ controls stability and generalization.
- "higher capacity" is needed to discriminate small deformations.

Questions:

- Better regularization?
- How does SGD control capacity in CNNs?
- What about networks with no pooling layers? ResNet?

## Outline

## Learning graph representations

State-of-the-art models for representing graphs:

- Deep learning for graphs: graph neural networks (GNNs);
- Graph kernels: Weisfeiler-Lehman (WL) graph kernels;
- Hybrid models attempt to bridge both worlds: graph neural tangent kernels (GNTK).

## Learning graph representations

State-of-the-art models for representing graphs:

- Deep learning for graphs: graph neural networks (GNNs);
- Graph kernels: Weisfeiler-Lehman (WL) graph kernels;
- Hybrid models attempt to bridge both worlds: graph neural tangent kernels (GNTK).

Our model:

- A new type of multilayer graph kernel: more expressive than WL kernels;
- Learning easy-to-regularize and scalable unsupervised graph representations;
- Learning supervised graph representations like GNNs.

## Graphs with node attributes

- A graph is defined as a triplet $(\mathcal{V}, \mathcal{E}, a)$;
- $\mathcal{V}$ and $\mathcal{E}$ correspond to the set of vertices and edges;
- $a: \mathcal{V} \rightarrow \mathbb{R}^{d}$ is a function assigning attributes to each node.

## Graph kernel mappings

- Map each graph $G$ in $\mathcal{X}$ to a vector $\Phi(G)$ in $\mathcal{H}$, which lends itself to learning tasks.
- A large class of graph kernel mappings can be written in the form $\Phi(G):=\sum_{u \in \mathcal{V}} \varphi_{\text {base }}\left(\ell_{G}(u)\right) \quad$ where $\varphi_{\text {base }}$ embeds some local patterns $\ell_{C}$
(Shervashidze et al., 2011; Lei et al., 2017; Kriege et al., 2019)

## Graph kernel mappings

- Map each graph $G$ in $\mathcal{X}$ to a vector $\Phi(G)$ in $\mathcal{H}$, which lends itself to learning tasks.
- A large class of graph kernel mappings can be written in the form

## Graph kernel mappings

- Map each graph $G$ in $\mathcal{X}$ to a vector $\Phi(G)$ in $\mathcal{H}$, which lends itself to learning tasks.
- A large class of graph kernel mappings can be written in the form

$$
K\left(G, G^{\prime}\right)=\sum_{u \in \mathcal{V}} \sum_{u^{\prime} \in \mathcal{V}^{\prime}}\left\langle\varphi_{\text {base }}\left(\ell_{G}(u)\right), \varphi_{\text {base }}\left(\ell_{G^{\prime}}\left(u^{\prime}\right)\right)\right\rangle .
$$

## Graph kernel mappings

- Map each graph $G$ in $\mathcal{X}$ to a vector $\Phi(G)$ in $\mathcal{H}$, which lends itself to learning tasks.
- A large class of graph kernel mappings can be written in the form

$$
K\left(G, G^{\prime}\right)=\sum_{u \in \mathcal{V}} \sum_{u^{\prime} \in \mathcal{V}^{\prime}} \kappa_{\text {base }}\left(\ell_{G}(u), \ell_{G^{\prime}}\left(u^{\prime}\right)\right) .
$$

## Basic kernels: walk and path kernel mappings

- Path kernels are more expressive than walk kernels, but less preferred for computational reasons.

## Basic kernels: walk and path kernel mappings

- $\mathcal{P}_{k}(G, u):=$ paths of length $k$ from node $u$ in $G$. The $k$-path mapping is

$$
\varphi_{\text {path }}(u):=\sum_{p \in \mathcal{P}_{k}(G, u)} \delta_{a(p)} \quad \Longrightarrow \quad \Phi(G)=\sum_{u \in \mathcal{V}} \sum_{p \in \mathcal{P}_{k}(G, u)} \delta_{a(p)}
$$

- $a(p)$ : concatenated attributes in $p ; \delta$ : the Dirac function;
- $\Phi(G)$ can be interpreted as a histogram of paths occurrences;

## A relaxed path kernel

$$
\varphi_{\text {path }}(u)=\sum_{p \in \mathcal{P}_{k}(G, u)} \delta_{a(p)}(\cdot)
$$

Issues of the path kernel mapping:

- $\delta$ allows hard comparison between paths thus only works for discrete attributes;
- $\delta$ is not differentiable, which cannot be "optimized" with back-propagation.

## A relaxed path kernel

$$
\begin{array}{r}
\varphi_{\text {path }}(u)=\sum_{p \in \mathcal{P}_{k}(G, u)} \delta_{a(p)}(\cdot) \\
\Longrightarrow \sum_{p \in \mathcal{P}_{k}(G, u)} e^{-\frac{\alpha}{2}\|a(p)-\cdot\|^{2}}
\end{array}
$$

Issues of the path kernel mapping:

- $\delta$ allows hard comparison between paths thus only works for discrete attributes;
- $\delta$ is not differentiable, which cannot be "optimized" with back-propagation.

Relax it with a "soft" and differentiable mapping

- interpreted as the sum of Gaussians centered at each path from $u$.

## One-layer GCKN: a closer look at the relaxed path kernel

- We define the one-layer GCKN as the relaxed path kernel mapping

$$
\varphi_{1}(u):=\sum_{p \in \mathcal{P}_{k}(G, u)} e^{-\frac{\alpha_{1}}{2}\|a(p)-\cdot\|^{2}}=\sum_{p \in \mathcal{P}_{k}(G, u)} \varphi_{\mathrm{RBF}}(a(p)) \in \mathcal{H}_{1} .
$$

- This formula can be divided into 3 steps:
- path extraction: enumerating all $\mathcal{P}_{k}(G, u)$;
- kernel mapping: evaluating Gaussian embedding $\varphi_{\text {RBF }}$ of path features;
- path aggregation: aggregating the path embeddings.

## One-layer GCKN: a closer look at the relaxed path kernel

- We define the one-layer GCKN as the relaxed path kernel mapping

$$
\varphi_{1}(u):=\sum_{p \in \mathcal{P}_{k}(G, u)} e^{-\frac{\alpha_{1}}{2}\|a(p)-\cdot\|^{2}}=\sum_{p \in \mathcal{P}_{k}(G, u)} \varphi_{\mathrm{RBF}}(a(p)) \in \mathcal{H}_{1} .
$$

- This formula can be divided into 3 steps:
- path extraction: enumerating all $\mathcal{P}_{k}(G, u)$;
- kernel mapping: evaluating Gaussian embedding $\varphi_{\text {RBF }}$ of path features;
- path aggregation: aggregating the path embeddings.
- We obtain a new graph with the same topology but different features

$$
(\mathcal{V}, \mathcal{E}, a) \xrightarrow{\varphi_{\text {path }}}\left(\mathcal{V}, \mathcal{E}, \varphi_{1}\right) .
$$

## Construction of one-layer GCKN

## From one-layer to multilayer GCKN

- We can repeat applying $\varphi_{\text {path }}$ to the new graph

$$
(\mathcal{V}, \mathcal{E}, a) \xrightarrow{\varphi_{\text {path }}}\left(\mathcal{V}, \mathcal{E}, \varphi_{1}\right) \xrightarrow{\varphi_{\text {path }}}\left(\mathcal{V}, \mathcal{E}, \varphi_{2}\right) \xrightarrow{\varphi_{\text {path }}} \ldots \xrightarrow{\varphi_{\text {path }}}\left(\mathcal{V}, \mathcal{E}, \varphi_{j}\right) .
$$

- Final graph representation at layer $j, \Phi(G)=\sum_{u \in \mathcal{V}} \varphi_{j}(u)$.

## From one-layer to multilayer GCKN

- We can repeat applying $\varphi_{\text {path }}$ to the new graph

$$
(\mathcal{V}, \mathcal{E}, a) \xrightarrow{\varphi_{\text {path }}}\left(\mathcal{V}, \mathcal{E}, \varphi_{1}\right) \xrightarrow{\varphi_{\text {path }}}\left(\mathcal{V}, \mathcal{E}, \varphi_{2}\right) \xrightarrow{\varphi_{\text {path }}} \ldots \xrightarrow{\varphi_{\text {path }}}\left(\mathcal{V}, \mathcal{E}, \varphi_{j}\right) .
$$

- Final graph representation at layer $j, \Phi(G)=\sum_{u \in \mathcal{V}} \varphi_{j}(u)$.
- Why is the multilayer model interesting ?
- applying $\varphi_{\text {path }}$ once can capture paths: GCKN-path;
- applying twice can capture subtrees: GCKN-subtree;
- applying more times may capture higher-order structures?
- Long paths cannot be enumerated due to computational complexity, yet multilayer model can capture long-range substructures.

## Scalable approximation of Gaussian kernel mapping

$$
\varphi_{\text {path }}(u)=\sum_{p \in \mathcal{P}_{k}(G, u)} \varphi_{\mathrm{RBF}}(a(p))
$$

- $\varphi_{\operatorname{RBF}}(a(p))=e^{-\frac{\alpha}{2}\|a(p)-\cdot\|^{2}} \in \mathcal{H}$ is infinite-dimensional;

## Scalable approximation of Gaussian kernel mapping

$$
\varphi_{\text {path }}(u)=\sum_{p \in \mathcal{P}_{k}(G, u)} \varphi_{\mathrm{RBF}}(a(p)) .
$$

- $\varphi_{\operatorname{RBF}}(a(p))=e^{-\frac{\alpha}{2}\|a(p)-\cdot\|^{2}} \in \mathcal{H}$ is infinite-dimensional;
- Nyström provides a finite-dimensional approximation $\Psi(a(p))$ by orthogonally projecting $\varphi_{\mathrm{RBF}}(a(p))$ onto some finite-dimensional subspace:
$\operatorname{Span}\left(\varphi_{\mathrm{RBF}}\left(z_{1}\right), \ldots, \varphi_{\mathrm{RBF}}\left(z_{q}\right)\right)$ parametrized by $Z=\left\{z_{1}, \ldots, z_{q}\right\}$, where $z_{j} \in \mathbb{R}^{d k}$ can be interpreted as path features.

## Scalable approximation of Gaussian kernel mapping

$$
\varphi_{\text {path }}(u)=\sum_{p \in \mathcal{P}_{k}(G, u)} \varphi_{\mathrm{RBF}}(a(p)) .
$$

- $\varphi_{\operatorname{RBF}}(a(p))=e^{-\frac{\alpha}{2}\|a(p)-\cdot\|^{2}} \in \mathcal{H}$ is infinite-dimensional;
- Nyström provides a finite-dimensional approximation $\Psi(a(p))$ by orthogonally projecting $\varphi_{\mathrm{RBF}}(a(p))$ onto some finite-dimensional subspace:
$\operatorname{Span}\left(\varphi_{\mathrm{RBF}}\left(z_{1}\right), \ldots, \varphi_{\mathrm{RBF}}\left(z_{q}\right)\right)$ parametrized by $Z=\left\{z_{1}, \ldots, z_{q}\right\}$, where $z_{j} \in \mathbb{R}^{d k}$ can be interpreted as path features.
- The parameters $Z$ can be learned by
- (unsupervised) K-means on the set of path features;
- (supervised) end-to-end learning with back-propagation.

## Comparison of GCKN and GNN

| GCKN | vs. |
| :---: | :---: |
| $f_{\mathrm{GCKN}}(G)=\sum_{u \in G} \psi_{k}(u)$ | $f_{\mathrm{GNN}}(G)=\sum_{u \in G} f_{k}(u)$ |
| $\psi_{k}(u)=\sum_{p \in \mathcal{P}_{k}(G, u)} \kappa\left(Z^{\top} Z\right)^{-\frac{1}{2}} \kappa\left(Z^{\top} \psi_{k-1}(p)\right)$ | $f_{k}(u)=\sum_{v \in \mathcal{N}(u)} \operatorname{ReLU}\left(Z^{\top} f_{k-1}(v)\right)$ |
| local path aggregation | neighborhood aggregation |
| projection in a known RKHS | $?$ |
| supervised and unsupervised | supervised |

## Experiments on graphs with discrete attributes

- Accuracy improvement with respect to the WL subtree kernel.
- GCKN-path already outperforms the baselines.
- Increasing number of layers brings larger improvement.
- Supervised learning does not improve performance, but leads to more compact representations.
(Shervashidze et al., 2011; Du et al., 2019; Xu et al., 2019; Kipf and Welling, 2017)

## Experiments on graphs with continuous attributes

- Accuracy improvement with respect to the WWL kernel.
- Results similar to discrete case.
- Path features seem presumably predictive enough.

## Model interpretation for Mutagenicity prediction

- Idea: find the minimal connected component that preserves the prediction.

## Outline

(6) Open Problems and Research Topics

- Multiple Kernel Learning (MKL)
- Large-scale learning with kernels
- Foundations of deep learning from a kernel point of view
- Motivation
- Deep kernel machines
- Deep learning and stability
- Application to graphs
- Application to biological sequences

## Sequence modeling as a supervised learning problem

## Sequence modeling as a supervised learning problem

- Biological sequences $\mathbf{x}_{1}, \ldots \mathbf{x}_{n} \in \mathcal{X}$ and their associated labels $y_{1}, \ldots, y_{n}$.
- Goal: learning a predictive and interpretable function $f: \mathcal{X} \rightarrow \mathbb{R}$

$$
\min _{f \in \mathcal{F}} \underbrace{\frac{1}{n} \sum_{i=1}^{n} L\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)}_{\text {empirical risk, data fit }}+\underbrace{\mu \Omega(f)}_{\text {regularization }}
$$

- How do we define the functional space $\mathcal{F}$ ?

## String kernels

A classical approach for modeling biological sequences over alphabet $\mathcal{A}$ relies on string kernels.

$$
K\left(x, x^{\prime}\right)=\sum_{u \in \mathcal{A}^{k}} \delta_{u}(x) \delta_{u}\left(x^{\prime}\right)
$$

where u is a $k$-mer over an alphabet $\mathcal{A}$ and $\delta_{u}(x)$ can be:

- the number of occurrences of $u$ in $\mathbf{x}$ : spectrum kernel (Leslie et al., 2002);
- the number of occurrences of $u$ in $\mathbf{x}$ up to $m$ mismatches: mismatch kernel (Leslie and Kuang, 2004);
- the number of occurrences of $u$ in $\mathbf{x}$ allowing gaps, with a weight decaying exponentially with the number of gaps: substring kernel (Lodhi et al., 2002).

What is $\Phi(x)$ ?
It can be interpreted as a histogram of pattern occurences.

## String kernels

A classical approach for modeling biological sequences over alphabet $\mathcal{A}$ relies on string kernels.

$$
K\left(x, x^{\prime}\right)=\sum_{u \in \mathcal{A}^{k}} \delta_{u}(x) \delta_{u}\left(x^{\prime}\right)=\left\langle\Phi(x), \Phi\left(x^{\prime}\right)\right\rangle
$$

where u is a $k$-mer over an alphabet $\mathcal{A}$ and $\delta_{u}(x)$ can be:

- the number of occurrences of $u$ in $\mathbf{x}$ : spectrum kernel (Leslie et al., 2002);
- the number of occurrences of $u$ in $\mathbf{x}$ up to $m$ mismatches: mismatch kernel (Leslie and Kuang, 2004);
- the number of occurrences of $u$ in $\mathbf{x}$ allowing gaps, with a weight decaying exponentially with the number of gaps: substring kernel (Lodhi et al., 2002).

What is $\Phi(x)$ ?
It can be interpreted as a histogram of pattern occurences.

## Convolutional kernel networks for sequence modeling

Define a continuous relaxation of the mismatch kernel (Chen et al., 2019a; Morrow et al., 2017)

$$
K_{\text {CKN }}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{i=1}^{|\mathbf{x}|-k+1} \sum_{j=1}^{\left|\mathbf{x}^{\prime}\right|-k+1} K_{0}(\underbrace{\mathbf{x}_{[i: i+k]}}_{\text {one } k-\mathrm{mer}}, \mathbf{x}_{[j: j+k]}^{\prime}) .
$$

- Use one-hot encoding

$$
\mathrm{x}_{[i: i+5]}:=\mathrm{TTGAG} \mapsto \begin{gathered}
\mathrm{A} \\
\mathrm{~T} \\
\mathrm{C} \\
\mathrm{G}
\end{gathered}\left[\begin{array}{ccccc}
0 & 0 & 0 & 1 & 0 \\
1 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1
\end{array}\right] .
$$

- $K_{0}$ is a Gaussian kernel over one-hot representations of $k$-mers (in $\left.\mathbb{R}^{k \times d}\right)$.

## Convolutional kernel networks for sequence modeling

Define a continuous relaxation of the mismatch kernel (Chen et al., 2019a; Morrow et al., 2017)

$$
K_{\mathrm{CKN}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{i=1}^{|\mathbf{x}|-k+1} \sum_{j=1}^{\left|\mathbf{x}^{\prime}\right|-k+1}\langle\varphi_{0}(\underbrace{\mathbf{x}_{[i: i+k]}}_{\text {one k-mer }}), \varphi_{0}\left(\mathbf{x}_{[j: j+k]}^{\prime}\right)\rangle
$$

- Use one-hot encoding

$$
\mathrm{x}_{[i: i+5]}:=\mathrm{TTGAG} \mapsto \begin{gathered}
\mathrm{A} \\
\mathrm{~T} \\
\mathrm{C} \\
\mathrm{G}
\end{gathered}\left[\begin{array}{ccccc}
0 & 0 & 0 & 1 & 0 \\
1 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1
\end{array}\right] .
$$

- $K_{0}$ is a Gaussian kernel over one-hot representations of $k$-mers (in $\left.\mathbb{R}^{k \times d}\right)$.

## Convolutional kernel networks for sequence modeling

Define a continuous relaxation of the mismatch kernel (Chen et al., 2019a; Morrow et al., 2017)

$$
K_{\mathrm{CKN}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\langle\underbrace{\sum_{i=1}^{|\mathbf{x}|-k+1} \varphi_{0}\left(\mathbf{x}_{[i: i+k]}\right)}_{\Phi(x)}, \underbrace{\sum_{j=1}^{\left|\mathbf{x}^{\prime}\right|-k+1} \varphi_{0}\left(\mathbf{x}_{[j: j+k]}^{\prime}\right)}_{\Phi\left(x^{\prime}\right)}\rangle .
$$

- Use one-hot encoding

$$
\mathbf{x}_{[i: i+5]}:=\text { TTGAG } \mapsto \begin{gathered}
\text { A } \\
\mathrm{T} \\
\mathrm{C} \\
\mathrm{G}
\end{gathered}\left[\begin{array}{ccccc}
0 & 0 & 0 & 1 & 0 \\
1 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1
\end{array}\right] .
$$

- $K_{0}$ is a Gaussian kernel over one-hot representations of k -mers (in $\left.\mathbb{R}^{k \times d}\right)$.

## Scalable Approximation of Kernel Mapping (with more details this time)

$$
K_{0}\left(u, u^{\prime}\right)=\left\langle\varphi_{0}(u), \varphi_{0}\left(u^{\prime}\right)\right\rangle_{\mathcal{H}_{0}} \approx\left\langle\psi_{0}(u), \psi_{0}\left(u^{\prime}\right)\right\rangle_{\mathbb{R}^{q}} .
$$

- Nyström provides a finite-dimensional approximation $\psi_{0}(u)$ in $\mathbb{R}^{q}$ by orthogonally projecting $\varphi_{0}(u)$ onto some finite-dimensional subspace:

$$
\mathcal{E}_{0}=\operatorname{Span}\left(\varphi_{0}\left(z_{1}\right), \ldots, \varphi_{0}\left(z_{q}\right)\right) \text { parametrized by } Z=\left\{z_{1}, \ldots, z_{q}\right\} .
$$

## Scalable Approximation of Kernel Mapping (with more details this time)

$$
K_{0}\left(u, u^{\prime}\right)=\left\langle\varphi_{0}(u), \varphi_{0}\left(u^{\prime}\right)\right\rangle_{\mathcal{H}_{0}} \approx\left\langle\psi_{0}(u), \psi_{0}\left(u^{\prime}\right)\right\rangle_{\mathbb{R}^{q}}
$$

- Nyström provides a finite-dimensional approximation $\psi_{0}(u)$ in $\mathbb{R}^{q}$ by orthogonally projecting $\varphi_{0}(u)$ onto some finite-dimensional subspace:

$$
\mathcal{E}_{0}=\operatorname{Span}\left(\varphi_{0}\left(z_{1}\right), \ldots, \varphi_{0}\left(z_{q}\right)\right) \text { parametrized by } Z=\left\{z_{1}, \ldots, z_{q}\right\} .
$$

- General case:

$$
\psi_{0}(u)=K_{0}(Z, Z)^{-1 / 2} K_{0}(Z, u)
$$

## Scalable Approximation of Kernel Mapping (with more details this time)

$$
K_{0}\left(u, u^{\prime}\right)=\left\langle\varphi_{0}(u), \varphi_{0}\left(u^{\prime}\right)\right\rangle_{\mathcal{H}_{0}} \approx\left\langle\psi_{0}(u), \psi_{0}\left(u^{\prime}\right)\right\rangle_{\mathbb{R}^{q}}
$$

- Nyström provides a finite-dimensional approximation $\psi_{0}(u)$ in $\mathbb{R}^{q}$ by orthogonally projecting $\varphi_{0}(u)$ onto some finite-dimensional subspace:

$$
\mathcal{E}_{0}=\operatorname{Span}\left(\varphi_{0}\left(z_{1}\right), \ldots, \varphi_{0}\left(z_{q}\right)\right) \text { parametrized by } Z=\left\{z_{1}, \ldots, z_{q}\right\}
$$

- Case of dot-product kernels $K_{0}\left(u, u^{\prime}\right)=\kappa\left(\left\langle u, u^{\prime}\right\rangle\right)$ :

$$
\psi_{0}(u)=\kappa\left(Z^{\top} Z\right)^{-1 / 2} \kappa\left(Z^{\top} u\right)
$$

linear operation - pointwise nonlinearity - linear operation (subject to interpretation)
Ex: $\kappa(\beta)=e^{\beta-1}$, polynomial, inverse polynomial, arc-cosine kernels....

## Single-Layer CKN for sequence modeling

## Multilayer CKN for sequence modeling

## From k-mers to gapped k-mers

## k-mers with gaps

- For a sequence $\mathbf{x}=x_{1} \ldots x_{n} \in \mathcal{X}$ of length $n$ and a sequence of ordered indices $\mathrm{I}=\left(i_{1}, \ldots, i_{k}\right)$ in $\mathbf{I}(k, n)$, we define a $k$-substring as:

$$
\mathbf{x}_{[1]}=x_{i_{1}} x_{i_{2}} \ldots x_{i_{k}} .
$$

- We introduce the quantity

$$
\operatorname{gaps}(1)=\text { number of gaps in index sequence. }
$$

- Example: $\mathbf{x}=$ ABRACADABRA

$$
\mathrm{t}=(4,5,8,9,11) \quad \mathbf{x}_{[]}=\operatorname{RADAR} \quad \operatorname{gaps}(\mathrm{ı})=3
$$

## Recurrent kernel networks

Comparing all the k -mers between a pair of sequences (single layer models)

$$
K_{\mathrm{CKN}}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{i=1}^{|\mathbf{x}|-k+1} \sum_{j=1}^{\left|\mathbf{x}^{\prime}\right|-k+1} K_{0}\left(\mathbf{x}_{[i: i+k]}, \mathbf{x}_{[j: j+k]}^{\prime}\right)
$$

- The kernel mapping is $\Phi(\mathbf{x})=\sum_{i=1}^{|x|-k+1} \varphi_{0}\left(\mathbf{x}_{[i: i+k]}\right)$.

## Recurrent kernel networks

Comparing all the gapped k -mers between a pair of sequences (single layer models)

$$
K_{R K N}\left(\mathbf{x}, \mathbf{x}^{\prime}\right)=\sum_{|\in|(k,|x|)} \sum_{\in \in \mid\left(k,\left|\mathbf{x}^{\prime}\right|\right)} \lambda^{\operatorname{gaps}(1)} \lambda^{\operatorname{gaps}(\jmath)} K_{0}\left(\mathbf{x}_{[]}, \mathbf{x}_{[]]}^{\prime}\right) .
$$

- The kernel mapping is $\Phi(\mathbf{x})=\sum_{\in \in \mathbf{I}(k,|\mathbf{x}|)} \lambda^{\operatorname{gaps}(1)} \varphi_{0}\left(\mathbf{x}_{[1]}\right)$.
- This is a differentiable relaxation of the substring kernel.

But enumerating all possible substrings is costly...

## Approximation and recursive computation of RKN

## Approximate feature map of RKN kernel

The approximate feature map of $K_{\text {RKN }}$ via Nyström approximation is

$$
\Psi(\mathbf{x})=\sum_{ו \in \mathbf{l}(k, t)} \lambda^{\operatorname{gaps}(\mathrm{I})} \psi_{0}\left(\mathbf{x}_{[1]}\right) \in \mathbb{R}^{q}
$$

where, as usual with a dot-product kernel, $\psi_{0}\left(\mathbf{x}_{[1]}\right)=\kappa\left(Z^{\top} Z\right)^{-1 / 2} \kappa\left(Z^{\top} \mathbf{x}_{[1]}\right)$.

- The sum can be computed by using dynamic programming (Lodhi et al., 2002),
- which leads to a particular recurrent neural network (see Lei et al., 2017).

## A feature map for the single-layer RKN

When $K_{0}$ is a Gaussian kernel, the feature map of RKN is a mixture of Gaussians centered at $\mathbf{x}_{[\mathrm{l}}$, weighted by the corresponding penalization $\lambda^{\operatorname{gaps}(1)}$.

$k$-mer kernel embedding

Figure: Example of $K_{\text {RKN }}$ for $k=4$

## Results

Protein fold classification on SCOP 2.06 (Hou et al., 2017) (using more informative sequence features including PSSM, secondary structure and solvent accessibility)

| Method | \#Params | Accuracy |  | Level-stratified accuracy (top1/top5) |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | top 1 | top 5 | family | superfamily | fold |
| PSI-BLAST | - | 84.53 | 86.48 | $82.20 / 84.50$ | $86.90 / 88.40$ | $18.90 / 35.100$ |
| DeepSF | 920 k | 73.00 | 90.25 | $75.87 / 91.77$ | $72.23 / 90.08$ | $51.35 / 67.57$ |
| CKN (128 filters) | 211 k | 76.30 | 92.17 | $83.30 / 94.22$ | $74.03 / 91.83$ | $43.78 / 67.03$ |
| CKN (512 filters) | 843 k | 84.11 | 94.29 | $\mathbf{9 0 . 2 4 / 9 5 . 7 7}$ | $82.33 / 94.20$ | $45.41 / 69.19$ |
| RKN (128 filters) | 211 k | 77.82 | 92.89 | $76.91 / 93.13$ | $78.56 / 92.98$ | $60.54 / 83.78$ |
| RKN (512 filters) | 843k | $\mathbf{8 5 . 2 9}$ | $\mathbf{9 4 . 9 5}$ | $84.31 / 94.80$ | $\mathbf{8 5 . 9 9 / \mathbf { 9 5 . 2 2 }}$ | $\mathbf{7 1 . 3 5 / \mathbf { 8 4 . 8 6 }}$ |

Note: More experiments with statistical tests have been conducted in our paper.
(Hou et al., 2017; Chen et al., 2019a)

Logos, by finding pre-image of each filter

## Results

Protein fold recognition on SCOP 1.67 (widely used in the past)

| Method | pooling | one-hot |  | BLOSUM62 |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  | auROC | auROC50 | auROC | auROC50 |
| SVM-pairwise |  | 0.724 | 0.359 |  |  |
| Mismatch |  | 0.814 | 0.467 |  |  |
| LA-kernel |  | - | - | 0.834 | 0.504 |
| LSTM |  | 0.830 | 0.566 | - | - |
| CKN |  | 0.837 | 0.572 | 0.866 | 0.621 |
| RKN | mean | 0.829 | 0.541 | 0.840 | 0.571 |
| RKN | max | $\mathbf{0 . 8 4 4}$ | $\mathbf{0 . 5 8 7}$ | $\mathbf{0 . 8 7 1}$ | $\mathbf{0 . 6 2 9}$ |
| RKN (unsup) | mean | 0.805 | 0.504 | 0.833 | 0.570 |

(Liao and Noble, 2003; Leslie et al., 2003; Vert et al., 2004b; Hochreiter et al., 2007;
Chen et al., 2019a)

## Conclusion of the course

## What we saw

- Basic definitions of p.d. kernels and RKHS
- How to use RKHS in machine learning
- The importance of the choice of kernels, and how to include "prior knowledge" there.
- Several approaches for kernel design (there are many!)
- Review of kernels for strings and on graphs
- Recent research topics about kernel methods

## What we did not see

- How to automatize the process of kernel design (kernel selection? kernel optimization?)
- How to deal with non p.d. kernels
- Bayesian view of kernel methods, called Gaussian processes.

[^0]:    ${ }^{a}$ https://en.wikipedia.org/wiki/Bernoulli_polynomials

[^1]:    ${ }^{2}$ a measure defined on all open sets

[^2]:    ${ }^{3} R$ is closed if, for each $A \in \mathbb{R}$, the sublevel set $\left\{u \in \mathbb{R}^{n}: R(u) \leq A\right\}$ is closed. For example, if $R$ is continuous then it is closed.
